Abstract. The signaling hypothesis has been vastly under investigation for many years. There are two attitudes towards this phenomenon; some believe that firms increase (decrease) their dividend to signal about the future increases in earnings due to asymmetric information that managers have. Adversely, others believe that firms usually increase their dividends when they do not have further lucrative projects with positive net present values. Although there is a lot of empirical testing about this hypothesis that has been placed, there is no investigation about agency costs and cheating potential signaling hypothesis can provide for managers to cheat shareowners and market if it happens in the stock market. Through this article, we will test the signaling hypothesis for the firms listed in Tehran Stock Exchange, a rather volatile emerging market. We concluded that while dividend increases have no significant information content about future earnings, dividend decreases have meaningful information content about decreasing earning in the future. We use different scenarios that managers can react if the signaling hypothesis occurs and analyze the agency cost these scenarios bear on shareowners.

Keywords: dividend policy; signaling theory; Agency cost; BCG matrix

1. Introduction

Dividend signaling theory states that managers use dividend changes to signal asymmetric information about the future profitability of the company, it seems that a study of changes in dividends and future profitability in the corporate finance field is a subject worth to be considered and discussed (Baker 2017). Probing the managers' perspective to dividend-paying, their purpose of it, and the issues they consider in dividend decisions, has long been a heated debate between scholars in the financial literature. For instance Smith (2017) analyses it in earning management context and James (2015) discover whether signaling theory and dividend paying increase social responsibility. In every financial market, whether in developed countries or emerging ones, why, how, and to what extent capital returns to investors is of great importance. On the other hand, the ability to transfer surplus values to productive investment opportunities is one of the crucial factors of economic growth. Although there are different works about testing signling theory, but research in developing markets, is not get to a conclusive stage (Abdulla 2016, Aivazian 2003).

In literature, three major methods are used to test this particular category of assumptions. The first method is to examine whether and how dividend changes can predict changes in future stock price. The second method tests whether and how dividend changes can predict the future accounting profitability of the firms. Specifically, with these two methods, if the assumptions are statistically accepted, it is claimed that companies use dividend changes as a harbinger of their future profitability. The third method, which is much less used and presumably has less power to corroborate or reject the hypothesis, is interviewing with corporate executives and financial officers and asking them about this approach to use dividend changes in order to signal about future earnings (Brav 2005, Baker 2002, Baker 2017).

One of the issues related to the signaling theory is to examine the relationship between dividend changes and future profitability changes. In fact, since managers' expectations of future profitability can be effective in firms' dividend-paying decisions, dividend changes, due to changes in the company's capital structure, can affect future profitability. Therefore, a robust and detailed econometric method is needed to investigate this endogenous relationship between dividend changes and profitability changes for a more accurate test of signaling theory.The first motive for this study is to investigate this endogenous relationship between dividend changes and future profitability changes, and this is done using a simultaneous equation method to control other effective variables. Another important issue is that this study is testing the theory in the emerging market of Iran. Literature has shown that in developing countries, it is necessary to think about certain considerations in the application of conventional financial theories. This happens for the higher risk of credit in both firms and countries, the existence of specific rules and laws for each country, the inability in using many common financial instruments (for example no existence of short selling in many countries' security market), the size of the capital market in comparison to the total assets, etc. (Booth, Aivazian, Demirguc-Kunt, Maksimovic (2001), Aivazian, Booth, Cleary (2003)). Here, we used the financial data of firms listed in Tehran Stock Exchange.

So far, many empirical findings of the impact of dividends on earnings have been inconclusive, in the sense that they have not led to a comprehensive conclusion; moreover, most of these studies have focused on developed countries such as the USA and UK. While there are limited researches of these kinds in developing markets, few studies have tried to research on the dividend determinants. Researches such as Adelegan (2003) in Nigeria, Ahmed and Attiya (2009), and Afza and Mirza (2010) in Pakistan, Al-yahyaee et al. (2006) in Oman and Al-Najjar (2009) in Jordan, and Baker et al. (2019) in Sri Lankan have been conducted on the factors affecting the dividend policy.

Other studies have also been carried out particularly to test the signaling hypothesis; other studies have also been carried out particularly to test the signaling hypothesis; again the results of these researches are

inconsistent with each other; this phenomenon is known as dividend puzzling which implies that there is no general rule for different markets. For example, studies in emerging markets by Lukose and Rao (2010) in India, Berezinets et al. (2018) in India, Chaudhary et al. (2016) in Pakistan, Travlos, Trigeorgis, and Vafeas (2001) in Egypt and Dasilas (2007) in Greek stock market, approved the truthfulness of the signaling hypothesis. Whereas studies by Berezinets et al. (2018) in Russia, Al Quadeh et al. (2015) in Saudi Arabia, Kadıoğlu and Öcal (2016) in Turkey, and Lotfi (2018) in the Tunisia stock market are inconsistent with the signaling hypothesis. In Iran, Talaneh (1991), Talaneh and Shemirani (2011), Khoshtinat and Hajian (2008), Ardekani et al. (2010), and Keshavarz et al. (2014) have conducted researches on the dividend policy, but these studies did not test the information content of dividend changes on future earnings.

Our first contribution is testing signaling hypothesis in one of developing countries, Iran. So we examine real data by using the information content of dividend announcements and its changes in the companies that are listed on the Tehran Stock Exchange during the period from 2001 to 2017 in Iran, a developing country. Due to limited access to data as well as incomplete and unstructured data, few studies have been conducted on dividend income in Iran. In this study, data were gathered in a variety of ways such as web page crawling. Finally, we put them in a structured, complete, and accurate manner in files to serve to analyze the research question in a wider domain and with much less error than similar local studies. Another contribution of this study is to take inflation as independent variable explaining some systematic changes in dividends and earnings. Iran, like many other developing countries, has suffered a high inflation rate over the recent decade. Therefore, with the inflation ranging from 14% to 30% per year, a hypothetical 20% increase in dividend may be justified barely by taking the effect of inflation into account. Hence, we considered inflation in our model as a meaningful factor to explain the changes in dividends and earnings. Furthermore, our last contribution is about how managers could react to the signaling potential of a dividend increase and decrease using the BCG growth-share matrix. Henderson (1979) developed the BCG matrix for analyzing various firms in corporate business portfolio. In current years, there is a new stream of research on how to apply the BCG matrix in different management issues. Smith (2002) applied the BCG matrix in customer profitability analysis and Widiatama et al. (2018) exploit the growth-share matrix in the market optimization era. We use the BCG growth-share matrix to predict the reaction of managers and different strategies they can take to communicate the stock market when they identified the signaling hypothesis is working.

The rest of this article is organized as follows. The second section reviews the literature for developed and developing markets, which ultimately finds a research gap in literature from the perspective of new source of data in emerging market, Iran. In addition, we find that how to react to the signaling hypothesis is one of the main issues managers would react to dividend strategy selection. The third section describes the data and measurement criteria. The fourth section presents the model used to analyze the data. The fifth section explains the findings of the tests, and the sixth section concludes the paper.

2. Literature review

Miller and Modigliani (1961) showed that with the assumption of several conditions, including the absence of taxes, transaction costs, and market imperfections, the market value of a company is entirely independent of its dividend policy. They came to the conclusion that the company's profitability and its investments are only factors affecting the firm's market value and stock price; the result of this study is called the dividend irrelevance hypothesis. Many theories after Miller and Modigliani have tried to show that dividend policy is important in future profitability. The main objection to Miller and Modigliani's theory is that this study is based on an efficient market. In other words, in an imperfect market, dividend policy can have an important effect on market value and future profitability.

One of the most critical issues in corporate finance is whether and how dividend changes contain information about future profitability. Although dividend signaling theories suggest that dividend increases signal more lucrative prospects (Bhattcharya 1979, Miller & Rock 1985), many empirical studies have failed to support this argument; for example, studies by Watts (1973), Penman (1983), DeAngelo et al. (1996), Benartzi et al. (1997), Grullon et al. (2002) have observed no or negligible evidence that dividend changes can predict future abnormal earnings. Also, some studies based on surveys and interviews from hundreds of financial managers have shown that managers deny the thought that dividends are used as a signaling device (Brav et al. 2005).

By reviewing literature, even with the assumption that the profitability of a stock is directly and positively correlated with the dividend increase announcements, whether the managers change dividends to signal the prospect of their firms cannot be tested with existing methodologies. In fact, it is possible for an investor to reasonably or unreasonably concludes that managers mostly use dividend changes as signals, which means that investors react positively (negatively) to dividend increases (decreases). While managers may have made this change for some other reasons (like investing for future growth). In addition, Watts (1973), Penman (1983), DeAngelo et al. 1996, Benartzi et al. (1997), Nissim and Ziv (2001), Grullon et al. (2002), Grullon et al. (2005), Brav et al. (2005), Denis and Osobov (2008), and others examined that dividend changes, instead of future stock returns, could predict subsequent accounting earnings. In short, no matter what the motive for dividend change is, what is noteworthy is that distributing dividends by itself may be effective in future profits.

In spite of some previous studies that imply a short span timing of information that dividend changes convey about future income, Increasing dividends by mangers are more likely when they predict a persistent increase in prospect earnings(Ham et al. 2019). According to this paradoxical results in the literature, a study by Kaplan and Perez(2019) shows changes in dividend payout should not be considered as a signaling tool, rather it's more aligned with the standard capital structure models. For example, Managers decide to pay out excess cash to shareholders when there are no investment opportunities.Considering dividend changes, since dividend increases reduce the amount of budget ready for newer investments, companies may lose potential investment opportunities with a positive net present value (NPV), or they will be forced to finance projects at a higher cost, while in either case, it may lead to a reduction in future profits. Also, in the Gordon (1962) model, it has been shown that in a stock portfolio with constant long-term expected returns, high dividend payouts will be offset by low expected earnings growth. In contrast, the agency theory (Jensen 1986; Jensen & Meckling, 1976) has a different view on dividend payouts. It is explained in the agency theory that due to the possibility of allocating resources to the activities that the managers themselves benefit from the most, increasing dividends can reduce the potential cost related to the agency problems. Meanwhile, corporate dividend payments are more closely monitored by the capital market as firms will visit the capital market with more frequency to meet their financing needs. This continuous monitoring by the capital market will not let managers deviate too much from the main guidelines that investors have in mind.

In an environment with asymmetric information, the dividend announcements and its changes have the potential to transfer internal managers' information to the outside. (Battacharya 1979, John & Williams 1985, Miller & Rock 1985). The assumption of signaling has been extensively tested in developed markets, and the results indicate that stock prices have a positive reaction to increase in dividends and negative reactions to decrease in dividends (Aharony et al. 1988, Borde et al. 1999, Eades et al. 1985, Impson 1997). Especially, Lukose, J., and Rao, S. (2010), investigated the theory of signaling in the Indian stock market and showed that dividend initiation has a much greater effect on the share prices than the increase in the dividend payout ratio.

Studies about the dividend signaling hypothesis generally track two different routes. One strategy has been to apply econometric methods to test the theories that are extant in the literature, and another has been to use the surveys filled by corporate executives about what the key dividend policy determinants are. Taking all the

reviewed theories in mind, one cannot imagine a unique direct impact of dividend changes on future profits, and it should be seen that excavating the data confirms which of the claims in this area.

In short, by excluding dividend change incentives, dividend-paying by itself can be effective in future profitability due to the change in the capital structure. Healy and Palepu (1988) indicated that firms that initiate (omit) dividends realize a significant increase (decrease) in their earnings for at least one year before and the year of dividend change. Similarly, these companies will have a significant increase or decrease in their profitability at least one year after the announcement. Benartzi et al. (1997) used a sample matching approach, in which firms that change dividends are matched with those that do not change dividend based on characteristics such as industry, past performance, and capital structure. Controlling for the earnings pattern and mean reversion, they found that there is no evidence to confirm that unexpected positive change in profitability (earning) occurs after dividend increases.

In contrast to these findings, Nissim and Ziv (2001) claimed that studies such as Benartzi were invalid due to the measurement error in the dependent variable and the problem with the omitted correlated variables. They assumed that current earnings were affected by the first-degree autocorrelation; after considering these problems and the arrangements for them, they found that positive dividend changes are related to changes in earnings for two years after the announcement. Their findings were remarkable because their predecessors who had used regression method reported an adverse result (Penman 1983), or did not find any relationship or found a very weak relationship. Pursuing a similar logic to that of Nissim and Ziv, Harada and Nguyen (2005) argued that the dispersion of the managers' motivation to set dividends might cause dividend change data to act in contrast to the signaling hypothesis.

In order to understand the potential nonlinear relationship between dividends and revenues, many of the former researchers incorporated methods other than ordinary linear regression analysis and reported different results from what Nissim and Ziv found. For example, DeAngelo et al. (1996) examined the dividend policy at times when company revenues were unexpectedly declining and concluded that dividend changes have almost no information about future changes in earnings. Similar results were also reported for the study of Grullon et al. (2002), and authors strongly rejected the claim of dividend signaling. Indeed, consistent findings in different studies with different methods, and often, in contrast to that of Nissim and Ziv, have raised the question of why companies pay dividends.

More recently, Lukose and Rao (2010) examined the stock price reaction to dividend changes and also the relevance of the signaling models in explaining the effects of dividend changes on the valuation of Indian industrial companies. This study analyzed the effect of dividend changes on corporate value, its impact on future profitability, and market response to dividend changes. They noticed the significant wealth effect around dividend changes during the year of changes, and it has been concluded that dividend changes have a significant and meaningful effect on the company's stock value and profitability in the same, but it will not be meaningful in the following years. Particularly, the initiation of dividend paying has a much greater effect than an increase in the payout on increasing the stock prices. Similarly, Liu and Chen (2015) tried to test the dividend signaling hypothesis as to whether managers change dividend profits to signal their expectations of profitability using the simultaneous equation and the data of US companies. Their results showed that managers change dividends to signal equity-scaled rather than asset-scaled earnings prospects. Also, they found evidence that managers change dividends to signal previous earnings changes.

So far, most studies have been concerned with developed markets. In emerging and developing countries we can find a study in Cairo has been carried out by Travlos et al. (2001), which examines the market response to increasing dividends and stock dividends and found that both cases have a significant positive effect on stock returns. In another emerging market, Dasilas (2007) has also seen significant market responses on dividend

changes in the Athens Stock Exchange. The study, conducted in Greece, examines the market reaction (price effect and volume of trades) to dividend payout announcements by companies. The article states that the structure of the Athens stock market has the following structural differences with other large stock markets. First, dividends in Greece are paid annually rather than quarterly or semi-annually. Second, the Greek corporate laws designate an accurate minimum amount for distribution from the taxed corporate profits. Third, neither tax on dividends nor capital gains is imposed. Fourth, the Greek listed firms are characterized by high ownership concentration where major owners are usually involved in the management and have, therefore, less need for dividend announcements as an information source. Despite all these differences, especially the absence of tax, circumstances seem to be very close to that of Miller and Modigliani dividend irrelevance theory, but this study demonstrates that the dividend announcement has a significant impact on stock prices and future earnings of companies in Greece, which well supports the signaling theory, and highlights the importance of further investigations.Zhao (2016) confirmed the signaling hypothesis by testing the relationship between dividend changes and corporate bond responses. Dividend increase(decrease) leads to a significant increase(decrease) in bond yield. Chaudhary et al. (2016) confirmed the signaling hypothesis by examining the Pakistan stock market reaction to dividend change. Liaqat et al. (2019) have researched the managerial perception about the signaling effect of dividend policy in Pakistan stock exchange as an emerging market. Their study indicates that current earning, past dividends, liquidity, taxation, managerial perspective, investor perception, and share prices have considerable influence on dividend policy. Furthermore, they concluded that the previous year dividend payout has not (or has a weak) effect on the estimation of the current year dividend payout. The other finding of this research is that continuing payout of the dividend could be considered as management performance and convey a positive signal to the market.

Lotfi (2018) shows the Tunisia stock market didn't approve truthfulness of the information content of dividend policy, but when there is a decrease in dividend payout, Lotfi(2018) reports a negative reaction by Tunisia stock market to the announcement of dividend policy.Another study has been conducted in the kingdom of Saudi Arabia stock market (Tadawul) by Al Quadeh et al. (2015). According to their conclusion, there is no significant market reaction to dividend announcements. Thus we could not generalize signaling theory to all kinds of markets. This study enlists the limitations and characteristics of KSA market and emphasizes that limitations of emerging markets have a significant effect on the feasibility of the signaling theory. A study by Kadıoğlu and Öcal (2016) in the Turkish stock market reported that there is no significant effect of dividend announcement on stock price, but they found a significant correlation between the increase in stock prices and with the profitability of previous year. A similar study conducted by Tran and Mai (2015) in the Vietnamese stock market; found that different kinds of dividend announcements (increase, decrease, and no change) have a positive effect on stock prices. Berezinets et al. (2018) found a similar result by analysis of Russia stock market during economic growth, in other words, they report a negative reaction to both increase and decrease in dividend policy, but their result for India stock market during economics growth is consistent with signaling theory. The reaction of both Russia and India markets to decrease in dividend are more considerable than to increase in the dividend.

Using regression analysis for causal inference, Tao et al. (2016) investigated the signaling hypothesis in China stock market under a distinctive and special rule called by authors **"**a semi-mandatory dividend policy**"**,   that forces firms to pay a minimum level of dividends to be allowed to do seasoned equity offering (SEO). They found a significant and meaningful positive relationship between an increase in dividend policy and future return for non-SEO firms, but for SEO firms there wasn't such a significant relationship, hence the SEO firms' result is inconsistent with the signaling hypothesis. According to such results, we should emphasize the distinctive behavior of different markets and different categories of stocks in each market. As another example, the effect of a firm's characteristics on signaling behavior is investigated by Gupta and Aggarwal(2018). By analysis of the Indian stock market in three-segment, they found that only mid-cap stocks confirm signaling effect when dividends increase, whereas a change in dividends of small and large-cap stocks didn't affect post-event behavior of the market. Some mix reaction also report in developed and developing market.Literature implies that this is

not necessary to see similar reactions by the market to dividend change announcement and dividend initiation announcement. For example, by examining stocks in CSRP(the Center for Research in Security Prices) dataset during 1990-2009, Smith and Pennathur (2017) found that dividend increase approves the signaling hypothesis, but dividend initiation effect doesn't support signaling. Rabbani (2017) found a difference between the effect of a dividend increase and a dividend decrease on the market reaction of Bangladesh stock market; whereas dividend decrease supports the signaling hypothesis, dividend increase does not approve it.Nam (2018) researched the role of R&D on the dividend decision of loss firms; her results support the signaling hypothesis for loss firms with high R&D activity in South Korea.

Although there are different studies in both developing and developed market but analyzing signaling hypothesis when there is tough economic condition is rarely investigated. A recent study by Khanal and Mishra (2017) focused on the reaction of the market to the dividend announcement in USA markets during the 2006-2012 period which referred to as a "sluggish economic period" by authors. They reported consistency with signaling theory in their findings during this period like previous researches on USA markets, but they underscore the considerable difference in the magnitude of the reactions, about 1.81% abnormal return in 2006-2012 period compared to 5.9 % results of previous research on the identical dataset when economy underwent high inflation and tax reform in 1980s.Gafoor et al. (2014) in their research findings indicate that there is a positive relationship between inflation and dividend payment policy. After consideration of the result of this study, along with findings of other similar researches in emerging markets (Baker et al. 2018), it should be emphasized on the importance of inflation impact when dealing with dividend decision issues (Baker and Jabbouri 2016, 2017).In this regard, Basse (2019) by controlling inflation, reinvestigate the dividend decisions of insurance companies of the Euro Stoxx stock market.

To date, a limited investigation about the impact of dividend policy on future profitability has been performed based on Iranian companies. In general, research on the financial market and securities of Iran has suffered too much generalization or other scientific problems due to the lack of access to high quality and structured data. In other words, data limitations are one of the essential factors leading to simplified models and entering analysis errors that directly affect the accuracy, validity, and reliability of the results of previous researches in Iran. In the present paper evaluate the information content of dividend changes in companies listed on the Tehran Stock Exchange during the period from 2001 to 2017. Having accessed, prepared, and aggregated the relevant non-structured and incomplete data, we are able to analyze the research question in a wider domain, with a more accurate analysis model, and much less error than former local investigations.

In addition, literature shows that there is no research on how managers could react to the signaling potential of dividends and what strategies they would take in different conditions. Furthermore, one can easily found cheating potentials when the signaling hypothesis happens in either direction. The main contribution of this research is to identify those potentials in different scenarios using the BCG matrix and clarify the state of each business when signaling potential happen. This would help shareholders to minimize their risk of having each share when the signaling hypothesis happen.

3. Data and measurements

Data gathering was the most significant milestone of this study. The data we needed to perform the tests was as follows (from 2001 to 2017, beginning and end of years are matched with the Persian calendar):
Aggregated data of dividends paid to stockholders;
Earnings per share for all stocks listed on TSE for all or a part of the time interval;
Adjusted close price of all stocks listed on TSE for all or a part of the time interval;

Aggregated data of Book value per share for all stocks in all of the years that firm is listed on TSE within the interval;
Some of the financial ratios of all firms listed on TSE in all or part of the time interval.

Since most of the data above were not neatly extant in any accessible database as a whole, and the others were only accessible only for a part of companies, we finally gathered the required data with a combination of web crawling and programmed robots (Octoparse, developed by Selenium) in conjunction with TSE client software.
Because the data were collected with different methods and from different databases, they needed to be integrated so that the necessary information for analysis would be structurally available. The process of cleaning and preparing collected data was arranged using Python programming to prepare the final data frames and making data ready for analysis.

Table 1 provides a descriptive view of dividend change frequency in TSE. Each column declares the number of records in that year for each of the dividend event types: increase, no change, and decrease. In this table, even a one IRR increase or decrease in dividends is considered as a change. According to Table 1, the dispersion of the dividend changes in the TSE is quite frequent.

4. Methodology and Analysis

4.1. Core concept and main process

In this research, we follow four steps in analyzing the signaling hypothesis and strategy reactions of a manager. Figure one shows this process for analyzing and predicting management behavior to signaling hypothesis when it is identified in the market. First, we determine whether the signaling hypothesis happens or not. In step two, we calculate the amount of dividend concerning all factors except for signaling hypothesis such as competition and so on. In step three, we find the position of the firm in the BCG growth-share matrix. This helps to understand the status of the firm in the market. In step four, we select the strategy to communicate the market considering the signaling hypothesis.
Figure 1. The process of applying signaling hypothesis to the firm

4.2. Determining signalling hypothesis

For selecting the best strategy to react to the market by managers, First, we need to identify whether the signaling hypothesis is happen or not in a specific market. We want to uncover this hypothesis in one of the main emerging markets, Iran. Considering figure 1 for the main methodology that this paper is based on, this can be used in all markets and it is not limited to the example we go through. In this part, we mostly followed the methodology used in Nissim and Ziv (2001). We first start with more simple models, which actually may lead to erroneous results. Then we discuss the faults of these models and try to solve them to propose the final model.

Table 1. Statistic description of dividend events

Year	Div-Inc	Div_No Change	Div-Dec	Total Div Events
2001-2002	119	17	86	222
2002-2003	97	14	127	238
2003-2004	160	25	107	292
2004-2005	137	31	127	295
2005-2006	155	86	127	368
2006-2007	150	73	147	370
2007-2008	167	81	132	380
2008-2009	146	63	139	348
2009-2010	147	74	126	347
2010-2011	175	91	121	387
2011-2012	222	108	132	462
2012-2013	259	98	127	484
2013-2014	310	95	126	531
2014-2015	194	108	258	560
2015-2016	157	134	301	592
2016-2017	177	149	245	571

The first method, assuming that the earnings follow a random walk process with a specific drift, uses a simple method like that of Benartzi (1997). In this model, the dependent variable is the changes in annual earnings deflated with price, and the rate of annual dividend changes is used as the independent variable. Specifically here, the relationship between dividend income change in year zero and the change in earnings in years zero, one, and two (deflated with the price at the beginning of the fiscal year of dividend distribution) is investigated, and the research question hypothesis will be tested. Therefore we regress the following equation for $\tau = 0$, 1, and 2.

$$\frac{E_\tau - E_{\tau-1}}{P_{-1}} = \alpha_0 + \alpha_1 R\Delta DIV_0 + \varepsilon_\tau \qquad (1)$$

In this equation, E_τ denotes earnings in year τ, P_{-1} is the stock price at the beginning of the dividend change year, and $R\Delta DIV_0$ is the rate of change in dividend per share in the year zero.

Table 2 has the results of this pooled OLS. The first row reports the coefficient and the second row reports t-statistic.

Conforming to Benartzi (1997), α_1 is positive and highly significant for $\tau = 0$, and it is not significant for $\tau = 2$, but, contrary to their findings, it is also significant for $\tau = 1$.

Table 2. Result of Model (1)

$\dfrac{E_\tau - E_{\tau-1}}{P_{-1}} = \alpha_0 + \alpha_1 R\Delta DIV_0 + \varepsilon_\tau$				
τ	α_0	α_1	R^2	N
0	-0.0146	0.0211	0.028	4639
	-2.253	11.469		
1	0.0015	-0.005	0.002	4479
	0.236	-2.769		
2	-0.0099	-0.0028	0.001	3957
	-1.495	-1.49		

Nissim and Ziv vastly argue that this simple model has ample faults. Firstly, it may have a measurement error in the dependent variable. The change in the earnings in equation (1) is deflated by price at the beginning of dividend change year (P_{-1}). Since price is reflecting stockholders' future predictions itself, abnormal positive (negative) change in earnings will indicate itself in rising (falling) prices. Therefore, the nominator and denominator of the independent variable in equation (1) are positively related to each other, and this measurement error may cause α_1 to be biased against finding information content in dividends. Thus, we exchanged the P_{-1} in this equation with B_{-1}, the book value of equity per share, which has no or little information about future earning changes as it changes once a year in Iran in most cases. Secondly, the assumption of earnings following a random walk pattern implies that the expected change in earnings may be zero (or constant if there is a drift). Nevertheless, in the presence of additional information about the company, this assumption may not hold anymore. Ohlson and Penman (1982) showed that ROE is an important predictor of changes in earnings. Based on their findings, ROE is mean reverting, which implies that low (high) earnings will follow high (low) levels of ROE. Hence, predicted changes in earning are negatively correlated with ROE. In order to solve the problem of this omitted correlated variable, ROE of the year $\tau - 1$ has been added to the model as an independent regressor, and the following equation will be used for $\tau = 0$ and 1.

$$\frac{E_\tau - E_{\tau-1}}{B_{-1}} = \alpha_0 + \alpha_1 R\Delta DIV_0 + \alpha_2 ROE_{\tau-1} + \varepsilon_\tau \quad (2)$$

In this panel data, to address the problem of heteroscedasticity and autocorrelation in residuals, we incorporated the Fama-Macbeth two-step regression procedure.

We know that dividend changes are highly correlated with the contemporary (same year) earning changes. Therefore, if we had autocorrelation in earning change series, we would see significant relations between dividend changes and earning changes in subsequent years. In this regard, we added $\frac{E_0 - E_{-1}}{B_{-1}}$ to the equation as a control variable to address this issue. Furthermore, it seems reasonable that the results about the information content of dividend changes may be asymmetric for dividend increases and decreases. Therefore, we add two binary dummy variables to separate the effect of these two events from each other, and we reach the following model for $\tau = 0$ and 1.

$$\frac{E_\tau - E_{\tau-1}}{B_{-1}} = \alpha_0 + \alpha_{1p} DPC_0.R\Delta DIV_0 + \alpha_{1n} DNC_0.R\Delta DIV_0 + \alpha_2 ROE_{\tau-1} + \alpha_3 \frac{E_0 - E_{-1}}{B_{-1}} + \varepsilon_\tau \quad (3)$$

In table 3, which will be provided further, we have the results of pooled and cross-sectional OLS regressions of models (2) and (3) including t-statistic for each coefficient and proportion of positive coefficients in each cross-sectional regression. In the analysis of cross-sectional regressions, we have used Fama-Macbeth method.

According to the results (Table3), none of the coefficients in model 2 is statistically significant, meaning that, based on this model, in the Iranian stock market, the dividend change rate, as well as the ROE, provides no useful information about changes in earnings (adjusted to book value) in the coming years. The reason for this observation can be the homogeneity of the book value of equity in the Iranian market, which extracts out the explanatory power from these variables. Particularly, because of the high inflation that exists in Iran, usually after a few years, the book value of equity per share will be completely irrelevant to the real value of equity since firms usually do not revise their capital in their balance sheet regularly. It should be noted, however, in the cross-sectional analysis, it was observed that these coefficients were statistically significant in some of the years while not in aggregation.

Table 3. Result from Model (2) and Model (3)

So far, in all three models, we just dealt with rates; in other words, earnings were deflated by a related value in all models. Now, it comes to mind why we do not regress the level of earnings on the level of changes in dividends. Therefore, now we put earnings as the dependent variable in our model. To make sure about the unbiasedness of estimators, we control for the current year earning (E_0). Moreover, we generally add three

categories of control variables: past accounting variables such as book value per share at the beginning of the dividend change year (B_{-1}) and the earning in that year (E_{-1}), the market price of stocks (P_{-1}), and the changes in dividend level (ΔDIV_0). Like in the model (3), we allow for different coefficients on past dividend increases and decreases. We will test the following equation coefficients for $\tau = 1, 2, 3, 4,$ and 5.

$$E_\tau = \beta_0 + \beta_{1\tau} DPC_0.\Delta DIV_0 + \beta_{2\tau} DNC_0.\Delta DIV_0 + \beta_{3\tau} E_{-1} + \beta_{4\tau} B_{-1} + \beta_{5\tau} P_{-1} + \beta_{6\tau} DIV_{-1} + \beta_{7\tau} DPC_{-1}.\Delta DIV_{-1} + \beta_{8\tau} DNC_{-1}.\Delta DIV_{-1} + \beta_{9\tau} E_0 + \varepsilon_\tau \quad (4)$$

The results of the regressions in the model (4) are shown in table 4. Further, we designed a panel data and used Fama-Macbeth procedure. In this model, the variable $DPC_0.\Delta DIV_0$ is not so meaningful, but the variable $DNC_0.\Delta DIV_0$ in the third column has very meaningful results, suggesting/which suggests that dividend increases in Iran appear to be not necessarily indicative of future increasing revenues, but a reduction in dividends is a significant sign of a decline in future earnings of up to five years. It is only significant at the confidence level of 10% for the first year, but for the next years, it is significant at almost every level. Note that this result is precisely the opposite of the result that Nissim and Ziv (2001) came to in the US stock market. Also, in this regression of model 4, the three variables of past year dividend, share prices at the beginning of current year and last year's earnings have significant explanatory power, which, according to their definitions, is not surprising and is entirely justifiable.

The possibly wrong hidden assumption behind this model is that it has posed inflation to be low and not fluctuate so much because it is regressing the earnings of up until five years on some variables of the current year. However, the time value of money may bear harsh changes during even one or two years in Iran, a country which underwent consecutive over-thirty-percent inflations in some years. Therefore, the minimum expectation of people in Iran from earnings growth in future years is the compounded inflation rate of those years.

Therefore, since Iran has been experiencing significant inflation rate every year for at least the last two decades, inflation seems to have a direct impact on investors' expectation of future profitability and it should be taken into account in the model under consideration. In this regard, the question that arises at this stage of our research is how to account for the effect of inflation on investors' expectation of future profitability, and possibly on corporate managers' motivation to increase dividends.

In the Nissim and Ziv (2001) method, probably due to the relatively constant, low level of inflation in the United States (averaging below 2% per year in the last decade), there was no need for incorporating inflation rate into the analytical model or preparing the input data structures. For example, in an economy experiencing low inflation, dividend increases -even as small as 10 cents- are considered a real increase in dividends by investors. Nevertheless, in a country such as Iran whose economy has a high and varying inflation rate, at the end of a fiscal year, not only is a 50 IRR dividend increase of a share not considered as an increase, but perhaps a reduction in that dividends' real value as well.

Table 4. Result of model 4

Therefore, in the present study, we used a method to examine the effect of inflation on increasing investors' expectation of dividends growth. To study the Iranian market, which is undergoing high inflation rates, we selected a base year, the year 2001, and deflated all financial variables (amounts not rates) in the rest of the years to this base year with a compounded rate of annual inflation rates. For example, variables of the year 2003 are deflated to the base year 2001 with the year 2002 and 2003 inflation rates. In Iran, the Central Bank and Iranian Statistics Center, independently report inflation each year. We selected the inflation rates reported by the Central Bank of Iran, rearrange the data into the discounted variables, and re-ran the model 4 with this new deflated dataframe. in this model, named model 5 the statistic description of the dividend events are put in the table 5 - equivalent to table 1 for the deflated dividends- and coefficients of variables and test statistics are reported in the table 6. bear in mind that the equation for model 5 is the same as the equation in model and just the data is different.

Table 5. Statistic description of dividend events after deflation

Year	Div-Inc	Div_No Change	Div-Dec	Total Div Events
2001-2002	47	4	143	194
2002-2003	90	6	136	232
2003-2004	100	10	140	250
2004-2005	104	21	152	277
2005-2006	122	31	174	327
2006-2007	117	31	186	334
2007-2008	77	30	199	306
2008-2009	115	42	151	308
2009-2010	131	46	149	326
2010-2011	137	49	181	367
2011-2012	183	50	187	420
2012-2013	218	47	199	464
2013-2014	144	46	307	497
2014-2015	113	79	336	528
2015-2016	151	87	279	517
2016-2017	1999	580	2924	5503

As can be seen, taking into account the effect of inflation in subsequent years has caused a significant change in the results of the tables. The DNC0*ΔDIV0 variable, as before, has been significant over the next five years with relatively large test statistics and positive coefficients. This result indicates that if the real value of the dividend (the deflated amount) declines, the market will react negatively because it will be a relatively strong indication of a decline in the firm's future profitability. At the same time, we found that none of the cells in the column associated with the dividend increase are significant, and they have very small test statistics. It shows that the occasional dividend increases in Iran had no indication of future profitability increases, possibly because the firms did not have projects with a positive NPV in hand that needs cash. Thus, there is no need for shareholders money, and it is better to return it to its owners so that stock prices will not fall next year.

Table 6. Result after inflation

$$E_\tau = \beta_0 + \beta_{1\tau}DPC_0.\Delta DIV_0 + \beta_{2\tau}DNC_0.\Delta DIV_0 + \beta_{3\tau}E_{-1} + \beta_{4\tau}B_{-1} + \beta_{5\tau}P_{-1} + \beta_{6\tau}DIV_{-1}$$

Due to the autocorrelation of these two variables, the lags of these two variables were also included in the model. As can be seen, these later variables are statistically significant in contrast to the current year variables. Lag of increment DPC-1*ΔDIV-1 is significant up to four years with negative coefficients. In other words, dividend increases have a declining effect on future profitability with one year delay, which is fully explained by the DPC0*ΔDIV0 that indicates dividend increases are probably due to the lack of positive NPV projects and no need for liquidity.The decreasing dividend lag of DNC-1*ΔDIV-1 has not been significant in any year, which is well justified by the significance of the DNC0*ΔDIV0 variable in all of the years. In other words, the present variable has absorbed all the effects related to reducing the dividend. The control variables P-1, B-1, E-1, and E0 have been meaningful for some years as expected of their controlling role, which is in line with our expectation that these variables were actually included in the model to assure accuracy. The R^2 variable is about 61% in the first year and 44% in the second year, with a downward trend to the fifth year, which is exactly what we expect, and as we move away from the current year, this variable will show less explanatory power of the current year variables for future earnings. The level of R^2 in the early years is quite acceptable, and this indicates that the variables of this model have explained a significant portion of the level of profitability and its changes over the years.

4-3.Dividend Strategy selection for communicating the Market

According to figure one, we are now in a place to go forward.Managers can react to the signalling hypothesis for better communicating dividend strategies or even cheating the market. In addition, shareowners must predict this reaction to better understanding the managers for lowering agency costs. For discovering different scenarios, we must identify the position of the firm in the BCG Growth-share Matrix or equivalently in Industry life cycle model. Henderson(1979) argued that a business can position itself in one of the four items in a corporate portfolio.Also in an imaginary corporate one can imagine a corporate having only one business and position a business to find what strategy can use to enhance competitive advantage. For instance, a new company would be in question mark and after analysing the market can go to the Star position if shareowners invest enough amount of money to expand the market. When the market is matured, the business go to the cash cow position to Milk the owners with profit distribution and not investing anymore .In the End the shareowners must sell the business when it goes in the Dog position.Figure two better describe BCG growth-share Matrix.

Market growth rate	High	**Q**uestion Mark	**S**tar
	Low	**D**og	Cash Cow
BCG growth -share Matrix		Low	High
		Relative market share	

Figure 2. BCG growth-share matrix (Henderson, 1979)

For using the BCG the growth-share matrix in dividend strategy selection, First we compute the amount of dividend that a firm is planed to pay before knowing about the signaling hypothesis. It means the the company must compute the real dividend that they want to pay to shareowners regardless of knowing the result of the signaling hypothesis in the market (the right side of figure three). Second, we position the firm in the matrix. Third ,a manager could use the knowledge of signaling hypothesis to change the communication plan with the market based on the position the company has in the BCG growth-share matrix (the left side of figure three). Figure three shows the difference between what is want to do in dividend strategy before and after identifying the signaling hypothesis in the market. We assume that one of the four conditions could happen. We use the first category if the signaling hypothesis is not supported in any directions. In the second category, market data reveal there is signaling when the dividend gets increased and earning would be higher in the future but lowering dividend is not related to future earning. In the third category, decreasing the dividend is a signal of a lowering earning in near future but increasing dividend shows nothing to happen in the near future. In the last category, one can identify signaling in both directions and it means if we increase the dividend, the earning will be higher in near future and if we decrease the dividend, the earning will be lower in the next few years.For driling down more we go through each condition in detail:

No signaling identified

In this condition, what managers do in before and after signaling identification are the same in every level of the BCG Growth-share Matrix.There is no cheating potential and shareowners can trust whatever managers would claim about dividend.Equation 5 can explain this behavior in detail:

$$Q_C=Q_r,\ S_C=S_r, D_C=D_r, C_C=C_r \tag{5}$$

Where:

Q_r is the real dividend in the question mark position

Q_C is the communicated dividend in the question mark position

S_r is the real dividend in the star position

S_C is the communicated dividend in the Star position

D_r is the real dividend in the dog position

D_c is the communicated dividend in the dog position

C_r is the real dividend in the cash cow position

C_C is the communicated dividend in the cash cow position

It is needed to say that based on the logic of the BCG Growth-share Matrix,the amount of dividend increase from the question mark to the star and form the star to the cash-cow.But it decrease from the cash Cow to the dog .In brief equation 6 is true in real cases.

$$Q_r=0,\ 0=<S_r<=C_r,\ D_r<=C_r$$

$$\tag{6}$$

$$D_r=<C_r>=S_r>=Q_r$$

Only increase signaling identified

In this condition, if managers increase the dividend to deviate from the real dividend(that is computed before signaling identified), market (including shareowners) expect for increase earning in the near future so if firm locate in the question mark and the star cell would cheat the market and benefit for attracting huge amounts of investment because of incorrect signals. Also in the cash cow position the value of the company would go up incorrectly for pretending better future that shareowners could assume. Furthermore, in the dog position managers can have enough time for finding a buyer for the whole company to divest from industry.

Managers could cheat shareowners especially in the dog position when the company can pretend to be valuable by increasing dividend to shareowners when it is logically false for that position.

Shareowners cannot identify the exact position of the company (the dog vs the cash cow) when increase signaling happens and managers increase the dividend to cheat shareowners subsequently.Equation seven can show this unreal future that managers can make for shareowners in simple equations. Comparing equation six (the real) and seven (unreal for better communication using signaling hypothesis) can show cheating potential evidently.

$$Q_C>=Q_r,\ S_C>=S_r, D_C>=D_r, C_C>=C_r \tag{7}$$
$$D_C>=C_C>=S_C>=Q_C$$

Dividend policy before considering signaling hypothesis	**Dividend policy after considering signaling hypothesis**

When no signaling identified

DIV=Q_c	DIV=S_c
DIV=D_c	DIV=C_c

$Q_C=Q_r, S_C=S_r, D_C=D_r, C_C=C_r$

Only increase signaling identified

DIV=Q_c	DIV=S_c
DIV=D_c	DIV=C_c

$Q_C >= Q_r, S_C >= S_r, D_C >= D_r, C_C >= C_r$
$D_C >= C_C >= S_C >= Q_C$

Only decrease signaling identified

DIV=Q_r	DIV=S_r
DIV=D_r	DIV=C_r

$Q_r=0, 0=<S_r<=C_r, D_r<=C_r$
$D_r=<C_r>=S_r>=Q_r$

DIV=Q_c	DIV=S_c
DIV=D_c	DIV=C_c

$Q_C=Q_r, S_C=S_r, D_C=D_r, C_C=C_r$
$D_C=C_C >= S_C >= Q_C$

Signaling identified in both direction

DIV=Q_c	DIV=S_c
DIV=D_c	DIV=C_c

$Q_C >= Q_r, S_C >= S_r, D_C >= D_r, C_C >= C_r$
$D_C >= C_C >= S_C >= Q_C$

Figure 3. Signaling hypothesis and cheating potential

Only decrease signaling identified

In this condition, decreasing signaling can tell about bad earning in the future over the market. By understanding having decrease signaling potential in the market, managers would not decrease the dividend for protecting the firm for bad signals. In addition, they would not increase the dividend because of not signaling potential in the market. Therefore, equation eight could be true and no change between real and communicating dividend occur. The most important phenomenon that is shown in equation 8 is the equality between the cash cow and the dog dividend. This is the result of cheating potential that decreasing the amount of dividend could signal to the market for the dog position and managers do not want to communicate this truth to shareowners.

$$Q_C=Q_r,\ S_C=S_r,\ D_C=D_r, C_C=C_r \tag{8}$$
$$D_C=C_C>=S_C>=Q_C$$

Signaling identified in both direction

As managers know that signaling is identified in both directions, they could increase dividend for using signaling potential whenever possible. In addition, they do not decrease the amount of the dividend even in the dog cell of the BCG growth-matrix.Thus equation nine can result from this situation and the cheating potential exists the same as previous conditions but in a more and serious way.

$$Q_C>=Q_r,\ S_C>=S_r,\ D_C>=D_r,\ C_C>=C_r \tag{9}$$
$$D_C>=C_C>=S_C>=Q_C$$

Conclusions, managerial implication and Limitations

In this paper, we go to the process of applying the signaling hypothesis to the firm (figure two) that is fully described and applied in the whole paper. First, we analyze the Iranian stock market as an example of an emerging market that is rarely investigated for signaling hypothesis in previous research. We show that an increasing amount of the dividend has no signal to shareowners but decrease the payment to stock owners have a great signal (empirical contribution). Then we show that managers could cheat shareowners based on the position they have in the BCG Growth-Share Matrix (theoretical contribution). Based on our analysis in the example of the Iranian Market we must use the third scenario and take care of the dog position that managers could preserve payment to a dividend to pretend their business is going well as the cash cow position (managerial implication). This research shows and predicts the agency cost that managers can make for shareowners when they identified the signaling hypothesis is working in the stock market (theoretical contribution).

We have some limitations in our research. Prior empirical research show in most cases we have positive signaling or no signaling in the market. Therefore, all Scenarios we analyze in figure three assume managers want to react to positive signaling. In rare cases, we can identify negative signaling in the market, where increasing dividend signals negatively to the market, for instance, decreasing in earning and lowering the total value of the firm. In that case, you must analyze again and re-write the analysis. In this research, we forecast the managerial reactions

to the signaling hypothesis for the first time. I propose other researchers to test this modeling by analyzing managers in their market for better understanding the mechanisms and chains of actions and reactions.

Abstract. World experience in economic development over recent periods indicates that, despite periodically occurring crisis situations, including globalization processes appearing all over specific countries, Such situations consistently develop on a more accelerated scale. Undoubtedly, the crisis situation that developed in the world market in the first half of 2020 under the influence of COVID-19 on all economies of countries without exception has had a great influence, and the nature of such an influence will certainly be felt over the next several years. In this vein, the establishment of the rules applicable in a particular jurisdiction regarding the activities of controlled foreign companies is one of the mechanisms for any state to protect its own national tax base. Using this approach, the modern rules of tax regulation of controlled foreign companies provide for the establishment of special rules for the shareholders, acting as controlling persons in terms of profits obtained from their foreign companies. At the same time, the application of tax exemptions to the profits of controlled foreign companies is undoubtedly one of the riskiest operations, despite the fact that a wide list of grounds for their application may be provided for within the specific state. As a result of a study of the activities of controlled foreign companies operating within the framework of national jurisdiction, when analyzing the degree of influence of tax bases, a strongly pronounced linear relationship with a correlation coefficient of -0.93 was revealed. This circumstance made it possible to identify the following important feature for controlled foreign companies: financial corporations are no longer attracted by the option of being in a specific national jurisdiction; moreover, they are more focused on other jurisdictions, including low-tax or offshore ones. The correlation analysis revealed a strongly pronounced linear relationship between the tax base and the tax rates; however, in terms of controlled foreign companies, which are primarily subject to national legislation, the correlation coefficient amounted to +0.89, which characterizes the economic tendency to reduce their financial investments, despite the reduction of the actual tax rate. In turn, for controlled foreign companies, whose activities are regulated to a greater extent by foreign legislation, the correlation coefficient amounted to -0.93, which is characterized by a reflection of the greater economic effect of actual tax rate reduction according to the following scenario: the tax rate reduction represents more financial injections for a particular national jurisdiction. At the same time, against the background of the quite consistent and successful in specific areas unification of EU tax rules, the problem of the incoherence of the rules concerning controlled foreign companies versus national jurisdictions of both

EU member states and other countries remains open and relevant. This circumstance contains controversial issues regarding the legitimacy of the application of the general regime of controlled foreign companies, since taking into account the fundamental economic freedoms, which, in particular, are enshrined in the OECD Model Double Taxation Convention on Income and Capital, the legitimacy of establishment of the internal rules of controlled foreign companies for various kinds of challenges, including Brexit, are sufficiently controversial.

1. Introduction

The established procedure of doing business using the territories of several jurisdictions necessitates the state to pay close attention to the tax policy pursued not only in relation to corporate revenues within the jurisdiction. Attention should be paid to the taxation procedure when income is received by tax residents outside the country. This circumstance leads to a more detailed study of theoretical and practical aspects in the field of international taxation (Eshuis, 2014). At the same time, the consideration of cases of practical tax evasion through various international structures remains the indirect aspect. Consequently, this circumstance strengthens the need for a more detailed approach to study and procedure of reconciliation of the practical aspects of protection of the national tax base from its diversion (Aburto, 2007), taking into account the development of effective mechanisms to counter tax evasion, including the use of gray tax evasion schemes by foreign structures, etc.

In this regard, the establishment of rules (procedures) applicable in a particular jurisdiction regarding the taxation of controlled foreign companies (CFCs) is one of the mechanisms to protect their own national tax base. Using this approach, the state provides for the establishment of a taxation procedure for the shareholders (who are controlling persons) of a portion of the profits from their foreign companies (Sangiovanni, 2013). At the same time, a certain part of foreign companies may be outside the national jurisdictions using the preferential tax regimes (Grossule, 2020). Therefore, the procedure of doing business outside the national jurisdiction is not to a certain extent relevant for controlling persons when applying the provisions on CFCs, since the tax rules are leveled, and the tax obligations are equalized.

2. Literature review

There is an active interaction in the practical activities of the EU countries between fiscal authorities and tax fraud and tax evasion, as well as aggressive tax planning of the corporations. So, following the results of the 2013 meeting of the CFE fiscal committee (European Confederation of Tax Advisers) in Brussels, where the negative impact of fraudulent actions by taxpayers on the economies of the member states of the European Union was discussed, specific measures aimed at countering tax evasion were proposed (Aggarwal, 2011). This approach adequately indicates the increased attention of the entire world community to the financial situation within each country. Consequently, the states are uniting to stabilize the national economy and combat the "diversion" of the tax base and profits transfer (Hampl, 2020). Thus, the international taxation theorists Bertrand (2015) and Akamah (2018) proposed a general rule concerning CFCs, which to one degree or another is contained as separate elements of its definition: "if a company from one country is controlled by the persons who are simultaneously residents of another country and participants in this company, these persons will pay tax on all profits of this company, if this profit is transferred by them in order to avoid taxation". In this regard, the following conditions

can be distinguished for recognition of a company controlled in accordance with the legislation on CFCs for the jurisdiction of each country:

1) the legal entity belongs to the foreign company (Arregle, 2016);
2) the company is controlled by a person who is a tax resident;
3) tax evasion is a goal pursued upon receipt of profit, which is subsequently transferred to a foreign company (Huang, 2018).

To the extent that three conditions are met simultaneously, the resident will be obliged to pay the foreign company income tax in the respective country (jurisdiction). This approach is also applied in the Russian tax legislation. In particular, as a rule, a foreign organization is recognized as a CFC when the following conditions are met simultaneously: the company is not recognized as a tax resident of the country's jurisdiction, while the controlling person of the company is a company and (or) an individual recognized as the tax resident of the country (Nigamaev et al., 2018; Sazanov and Akhmetshin, 2016; Garnov et al., 2020).

It should be noted that in the opinion of Turishcheva (2020), provision of a decisive influence or the ability to exercise a decisive influence on the decisions made by such a company when distributing the profit (income) after taxation due to direct or indirect participation in such a company, participation in the contract (agreement), the subject matter of which is the company management, or other features between the person and the organization and (or) other persons, is recognized as control over the company.

Since the general tax rules for the CFCs, in the opinion of Akhmadeev (2019) and Morozova (2019), are not fully developed, accordingly, the national legislation governing the procedure for taxation and control over the activities of the CFCs must comply with international principles and norms contained in international treaties and acts (Almunia, 2018). In this regard, it is important to analyze national legislation for its compliance with international principles. In particular, they include: the principle of legality, the principle of equality, the principle of freedom of economic activity, etc. As a rule, the practice of taxation in relation to CFCs is a special legal institution that takes into account the basic foundations of the problems of business structuring both in national jurisdiction and beyond its limits, including relations with offshore jurisdictions, preventing the national jurisdiction from lagging behind the application of international agreements and the exchange of tax information.

In turn, the practical experience of application of the legislation on CFCs indicates the existence of various opinions of the economists Iurko (2018) and Arner (2020), pointing out the shortcomings of certain existing provisions. In particular, these shortcomings concern the established threshold for notification and income tax payment (Lehoux, 2019), the additional burden on businesses related to the translation of statements for national use (Kosov, 2016; Vertakova et al., 2019; Akhmetshin et al., 2019), and the absence of clearly established provisions distinguishing between revenues in various industry aspects (Bykanova, 2018; Rahman and Bobkova, 2016; Prodanova et al., 2019). To date, many issues have not been resolved, the legislation on CFCs in the framework of national regulation continues to be edited, amended, and improved (Petrova, 2019; Puryaev et al., 2019). In this regard, attention should be paid to the current procedure for determining CFCs, based on its criteria for individual states.

3. Theoretical background

In the international taxation practice, the general condition for the recognition of a person as a controlled one is the ability of the controlling person to influence it in any respect. At the same time, a legal standpoint involves the reservation on the attribution of the CFCs exclusively to the category of a foreign person. At the same time, the current procedure applied in most world countries in relation to CFCs recognizes a foreign legal entity (i.e., having a corporate form) and does not apply to their other forms, in particular, to foundations, trusts, etc.

It should be noted that in order to recognize a foreign company belonging to the CFC category, the current legal status of a state belonging to a particular jurisdiction is more applicable. This approach is used in countries such as the USA and Germany. The provisions of the OECD recommend the use of an expanded definition of the

CFCs in national jurisdictions. This is no coincidence since in this case, the scope of taxation will be used in relation to permanent missions. Consequently, if a taxpayer receives additional profit using permanent missions outside of national jurisdiction, the state will additionally receive budget revenues, taking into account the establishment of fair income tax rates and compliance with tax principles.

The definition of the CFCs is inextricably linked with the definition of tax residency. Moreover, the tax residency of companies and structures can be determined in various ways. In particular, states can recognize companies as foreign using both a formal criterion (existence of a place of incorporation of a company in a foreign state) or based on an expanded approach, for example, when establishing the role and place of the central government in a particular jurisdiction. In particular, the current German tax law contains a condition for the recognition of a foreign company as a controlled one. For this purpose, it must be registered in a foreign country in which the office is physically located and the company is managed. At the same time, a company is recognized as a tax resident of Germany if physically its office or its management is located in Germany. Respectively, the provisions of the internal legislation on CFCs are not applicable to this category of taxpayers.

In turn, from a legal standpoint in the UK, a stepwise approach is applied when classifying a company as a CFC. At the first stage, the company is tested on the basis of its place of residence in the relevant national jurisdiction. In the event that the company is registered in the United Kingdom, and its place of business is in another territory (outside its location), and such a person pays taxes, taking into account the nature of the effect of double taxation avoidance agreements, the fundamental value in determining the CFC will be the amount of income received in a specific jurisdiction. In this case, the amount of income received for the tax period must be at least 50% of the total. Directly, in the practice of taxation, disputes arise between taxpayers and tax authorities regarding the procedure of the place of residence of the CFC. In this regard, prominence should be given to the following criteria for the recognition of CFCs (Fig. 1).
Figure 1. Basic criteria for compliance with the recognition of the CFC
Source: compiled by the authors

It should be noted that when determining the location of a company to meet the criteria of the CFC, the states form special registers at the legislative level that correspond to different jurisdictions. In particular, the states or certain (offshore) territories that do not carry out the fair competition and are not included in the current procedure for mutual tax exchange of information between fiscal authorities in relation to both taxpayers and their transactions may be included in the illegal environment.

Special attention should be paid to the formation by the states of a separate list of jurisdictions, in which reduced tax rates are applied or the companies are completely tax exempt; therefore, in this case, the CFC taxation procedure may be justified from the point of view of obtaining additional tax revenues to the budget (Korableva et al., 2018). In addition to the criteria-based approach to the recognition of the persons attributable to CFCs, an important aspect is the current procedure for their profit taxation. In this case, the established procedure for calculating the taxable amount of profit, taking into account the legal qualifications of the transaction, is the most significant.

In general, the obtained value of the profit of the CFC shall be included in the tax base of the controlling person or in proportion to its participation or control. This taxation procedure is applied in most countries. Moreover, in most cases, the tax law of states contains significant elements of provisions that exclude the application of the general procedure for CFC taxation. However, an important aspect in taxation, in particular in Spain, Germany, and the USA, is the observance of "deminimis". This involves the cases when, in the calculation of the income received, the CFC is restricted to the limit of the established threshold values. In establishing the legal qualifications of a transaction in relation to the profits received by the CFC, the following concepts are applied:
1) the recognition of actual profit as the value of "supposed" dividends (fictitious distribution of profits);
2) the identification of the actual amount of profit in respect of the controlled person.

In this regard, when the taxpayer chooses the appropriate version of the concept, it will lead to the application of the legally established tax rules for the CFC, taking into account the current tax rates. At the same time, from the standpoint of tax administration rules, most states have a clear establishment of the procedure for annual notification by the taxpayers of the presence of CFCs on the basis of the presentation of established forms, as well as the procedure for providing grounds for exemption of the CFC's profits from taxation.

4. Data analysis

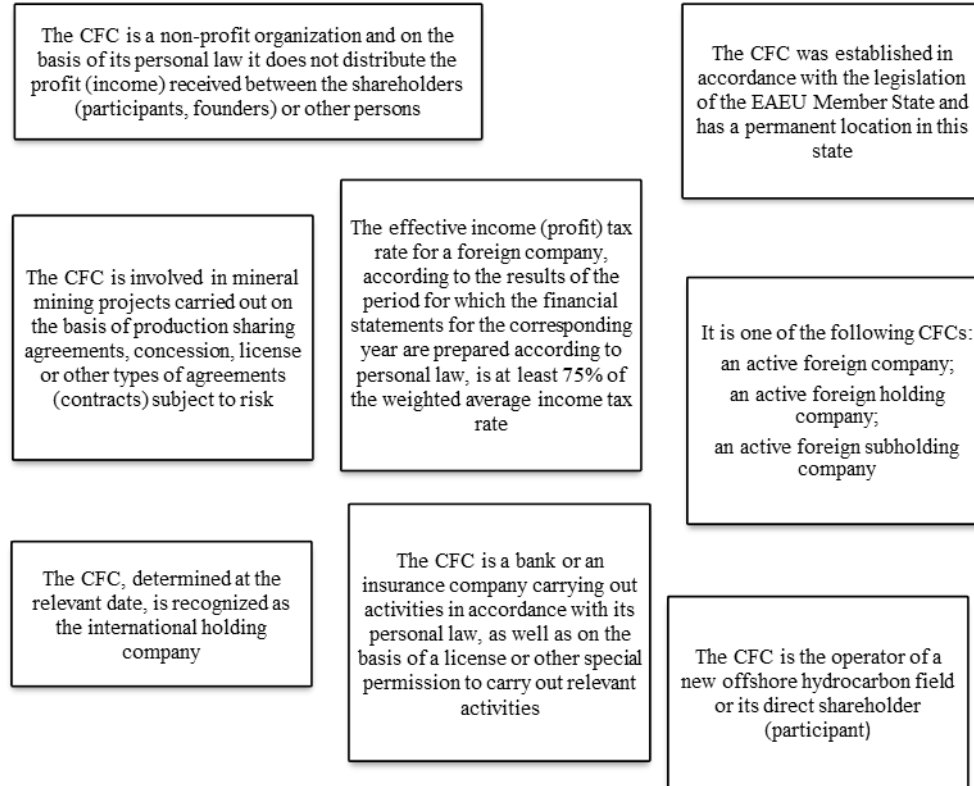
When considering the procedure for presenting the grounds for exempting the CFC's profits from taxation, taking into account the current taxation procedure, attention should be paid to the general list containing the conditions for their provision. Moreover, if at least one of the following conditions can be attributed to a specific CFC, then its profit is exempt from taxation on the basis of the general conditions provided in Figure 2.


Figure 2. Basic principles of the application of exemption from taxation of profits of the CFC by the example of national tax jurisdiction
Source: compiled by the authors

It should be noted that in order to exempt the CFC from taxation, it is also important to comply with the provisions regarding the legal aspects of circulating bonds and debt obligations and the mandatory presence of a valid international treaty in the field of taxation with an appropriate exchange of information established for these purposes between the national tax jurisdiction and the state in which the CFC is located on a permanent basis. This is the key condition for exemption of the CFC from income taxation.

When the CFCs participate in relevant mining projects, the following should be observed as a basis for granting tax exemption: the CFC is one of the parties to the contract, including: concession, license, as well as on the basis of production sharing agreement, or other types of contracts based on risk conditions. In this case, the foreign state (territory) or the government, as well as an institution authorized by it (for example, a state corporation) should be the other side of the concluded agreements. At the same time, there is an additional condition in the tax law regarding the application of the CFC income tax exemption: the share of income received in connection with participation in agreements for the period of preparation of financial statements for a financial year should be more than 90% of the total CFC income, as well as if there are no incomes for the relevant period in the financial statements, or consist of the amount of income in the form of exchange differences received or income not accounted for by their individual types, taking into account tax legislation.

It should be noted that the general terms and conditions of the tax law for exemption of the CFC from income taxation contain a closed list. If the CFC does not fit one of the criteria, then the controlling person is obliged to

pay tax on the profit received by the corresponding CFC. In order to apply tax exemption for any of the above reasons, the controlling person must submit to the tax authority at the place of location the documents confirming compliance with the conditions for exemption, translated into the national language of the jurisdiction in the part required for verification, together with the CFC notification in a timely manner. According to written explanations of the Federal Tax Service of Russia, the following is a valid list of supporting documents:

1) tax reporting of the CFC (Lehoux, 2018);
2) calculation of the effective income (profit) tax rate of the CFC and the weighted average corporate tax rate;
3) certificate of tax residence of the CFC for the corresponding period.

In juridical doctrine, the scope of application of exemption for CFCs' profits from taxation is considered one of the riskiest. Despite the fact that the legislative level provides a wide list of grounds for the exemption from taxation of the CFC's profits, in practical terms, there are a number of problems in the application of legal grounds. First of all, the taxpayers are required to calculate the effective tax rate in the country of their location equal to at least 75% of the Russian average weighted income tax rate. At the same time, according to the findings of Carruthers (2020), there is a contradictory opinion in the practical activity of controlling persons. For example, if such a person located in Germany applies a basic tax rate of more than 20%, then, when calculating the weighted average, the excess of 75% of the 20% income tax rate in national jurisdiction will be 75% ≈ 15%. Therefore, if the current tax rate in the country of location is approximately 15%, in this country the general income tax rate will be approximately the same number of percent, therefore, it is possible to apply exemption for such a company (Lampert, 2013). At the same time, the logic of such reasoning lacks the essential detail – the rate should be "effective". For example, in Switzerland, a different procedure is applied to provide benefits to individual companies, and the performance criterion is less than 15% (Seo, 2020).

Another controversial practical aspect is related to the exemption grounds for active foreign companies with passive income of at least 20% of their total income, or to subholding companies. The attention should be paid to the fact that tax legislation does not contain a definition of the "active income" concept. It may be advisable to follow logically from the opposite, i.e. to define it through the concept of passive income, and, which is extremely important, through the unclosed list of features. One way or another, the above legal norm contains standard varieties of passive income, including: interest, dividends, income from shares, income from the sale of shares in shares, income in the form of a liquidation premium, and royalties. It should be understood that if royalties with interest in aggregate account for more than 80% of the company's income, then such a company is not automatically considered an active foreign company; therefore, its profit is subject to income taxation according to the rules of national jurisdiction.

The list of such expense as the certain types of passive income, in particular, the income from the provision of services (more related to R&D, as well as development, research in the scientific field, marketing promotion services), rent, etc., may be open, and the main danger lies in the current wording "other ... similar income". Therefore, the tax risk lies in the fact that even if the CFC is engaged in the provision of any of the services mentioned above, for example, related to scientific studies of the activity of the drug, which then can lead to the sale of this drug in the territory of national jurisdiction, then anyway the fact of obtaining income from research activities may lead to the qualification of this income as passive, and here the legislatively established percentage boundaries should be taken into account.

Moreover, the amount of passive dividends that are not included in the calculation of income excluded on the basis of the granted exemption of the active foreign subholding companies relates to income from active foreign companies. At the same time, in this situation, the residents do not belong to foreign companies. Consequently, a resident acting as a subsidiary of a Cypriot organization will not meet the characteristics of an active foreign

company. Therefore, the indicated exemption will not be applicable if the dividends are received from the operating companies of national jurisdiction as the main income of a foreign company, therefore, the taxpayers have the right to defend their interests in court.

Analysis of the practice of tax regulation of legal acts in the EU countries
In the analytical part of the scientific study, it is important to analyze the existing problems arising from the legal regulation of the taxation of the CFCs in the countries of the European Union, based on the analysis of judicial practice, especially vivid, notable court decisions. Given the imbalance due to differences in existing EU law and the general rules governing CFC taxation (Gidirim, 2016), the case law of Cadbury Schweppes plc and Cadbury Schweppes Overseas Ltd v Commissioners of Inland Revenue should be reviewed. The precedent for the tax dispute is the following practical situation: the confectionery company Cadbury Schweppes (now in civil circulation under Cadbury plc) with a head office in London (the parent company) has established a number of subsidiaries in Ireland. However, these companies carried out financial activities without having an office or a staff of employees and also with no telephone communications. At the same time, in 2006, Ireland had a tax incentive that established a reduced tax rate of 10% of the company's profits, while in the UK the main tax rate was at least 30%. Thus, Cadbury Schweppes, in fact, carried out a tax optimization of its business.

The UK tax authorities, acting as the plaintiff, raised the issue of application of the CFC rules to the subsidiaries. In turn, Cadbury Schweppes, acting as the defendant, referred to economic freedoms within the framework of the EU Member States in the course of the lawsuit. At the same time, the judicial authorities accepted the defendant's position, noting the incorrectness of considering the level of taxation as the application of criteria to resolve the controversial issue of the applicability of the CFC rules within the EU. At the same time, as noted in the court decision, there is a situation in which it is possible to limit the entrepreneurial freedom of the company in the event of imitating economic activity and provided that the sole purpose is intentional tax evasion. In this regard, the position of the court is among the precedents in the field of international practice of CFC taxation.

Another landmark court decision for the EU in the field of research issues is the case "Vodafone 2 v. RCC". First of all, it is worth noting that Vodafone was (and is for the current tax period) one of the largest mobile operators. The case was heard in British and European courts. Initially, Vodafone sued for suspension of additional verification of the tax return. Its subsidiary was located in Luxembourg, and UK tax authorities were exploring the feasibility of applying British internal CFC tax rules. In turn, Vodafone referred to the case-law of Cadbury Schweppes and tried to prove that the CFC rules are applicable only in the case of circumvention or deliberate fraud of the tax system using various schemes. At the same time, the court of appeal agreed with the plaintiff Vodafone, taking into account the precedent and, thereby, confirming the conclusions about the inapplicability of the internal rules of the CFC to the CFC established and operating in another state. However, the court's opinion was narrower than the conclusions drawn in the Cadbury Schweppes case. So, from the standpoint of the judges, not all CFC incomes are subject to protection against taxation, but only in terms of the value added by the employees. Thus, the British court set itself a broader task: to correlate the findings of the Cadbury Schweppes precedent with the answer to the question of the possibility of exemption from the CFC rules at the level of the parent company of a subsidiary established within the EU. Having identified such a contradiction, the judges formed the following scenarios:
(1) to return the case again to the European Court, or
(2) to upgrade the existing CFC regulations (Delgado, 2017).

The correctness of the entrepreneurial freedom violation on the basis of counteraction to tax evasion is the key problem of European legal doctrine. As a rule, the Cadbury Schweppes case and the similar Columbus Container Services BVBA & Cov. Finanzamt Bielefeld-Innenstadt case is analyzed. It follows from the first of these cases that in the EU it is quite natural that the company seeks to optimize its operations in order to find a lower tax rate.

However, these actions do not indicate tax evasion (Yemelyanov et al., 2019). At the same time, the court needs to find out whether the CFC actually carries out the entrepreneurial activity in the country of its incorporation. The answer to this question depends on the resolution of the basic question of the applicability of the internal rules of the CFC profits taxation. As for the second of these trials, here the court evaded a direct answer to the analyzed question, thereby making narrower the analysis of the fact of discrimination. Therefore, this lawsuit did not become a precedent in deciding which of the tax principles prevails: territorial or global (Monsenego, 2012).

Thus, it is important to focus on the identified and relevant for the EU problem of the applicability of the internal national taxation rules for the CFC, which operates and is incorporated in the EU member state, but not at the place of incorporation or operation of the parent company. At the same time, there are other precedents in international legal practice that gives rise to unresolved issues, since the specifics of the current EU regulatory legislation in a particular state are not fully taken into account.

5. Results

Based on the example of one of the jurisdictions, let us carry out a correlation analysis of the tax base and tax rates, the results of which will make it possible to conclude that they are dependent. For the purposes of the study of the specifics of the CFC taxation, taking into account the current provisions of the Tax Code of the Russian Federation, regulating the procedure for accounting for the profits of CFCs in a general manner, non-operating incomes were also included in the composition of the income received. This procedure is general in tax base calculation for income tax for the taxpayers and Russian companies. In this case, the date of income to determine the CFC's profit is the end date of the period for which financial statements for the financial year are prepared on the basis of the law of the location (registration) of the unincorporated foreign company or structure (hereinafter – the UFC). In the event that the date can be determined by the personal law of the CFC, the date of receipt of income is recognized on December 31 of the year following the current tax period. If the personal law of the CFC does not imply an obligation to provide financial statements, the date of recognition of income will be December 31 of the current tax period, the last of which is the end date of the corresponding financial period.

In this regard, with the entry into force of tax legislation in 2015, in general, 2016 became the first year for the taxpayers to include the CFC's profit in the tax base, with mandatory inclusion of the CFC's profits for 2015, if the personal law of such a company required the preparation of a financial report for the current tax period. In particular, the annually updated tax return on income tax for the period of 2019 when calculating the income received in the form of profits of the CFC includes a separate appendix containing detailed transcripts by categories of taxpayers (Fig. 3).
Figure 3. Comparative dynamics of CFC activities in national jurisdictions in calculating the number of companies to the tax base
Source: The authors' research based on the data of https://www.nalog.ru/rn77/related_activities/statistics_and_analytics/forms/

It should be noted that when studying the average for the tax period number of CFCs operating under the personal law as of January 1, 2018, it decreased to 164 units, and over the next tax period the growth was 310 units.

In this case, the physical volume of the growth rate of the tax base as of January 1, 2019, compared to the same period as of January 1, 2017, was 32%, and the increase in the number of the CFCs operating under personal law for similar periods was 52%. The results obtained on the basis of the analysis of the influence of the tax bases on the CFCs under study showed a strongly pronounced linear relationship with a correlation coefficient equal to -0.93.

This approach is characterized by the following important circumstance: financial corporations are no longer attracted by the option of being in a national jurisdiction, and they focus more on other jurisdictions, including low-tax or offshore ones.

In turn, the dynamics of the number of the CFCs operating according to the rules established by national legislation showed a negative trend. At the same time, with regard to determining the tax base of controlling persons for the income in the form of profit received, the basic tax rate of 20% is applied. However, the tax base for calculation does not include the expenses received from other activities and the amount of losses incurred in relation to the activities of the controlling entities themselves. Moreover, the entire amount of the calculated tax is subject to transfer to the federal budget, without its distribution as for the main category of taxpayers. This involves payment of 3% of the income tax to the federal budget and 17% of profit payable to the budgets of the subject of the Russian Federation. The following documents are recognized as supporting and confirming the value of the calculated tax base and calculated tax:
   1) the income tax return and its annexes;
   2) the financial statements of the CFC for the relevant period and the audit report on these statements.

At the same time, this procedure is justified either by personal law or by constituent documents, in which a mandatory audit is established, including on a voluntary basis. Moreover, such documents of a foreign company must be translated into Russian.

In addition, certain clarifications of the Ministry of Finance of Russia contain an additional indication that the following can be used as supporting documents: the extracts from the CFC settlement accounts, primary documents confirming the operations performed in accordance with the company's business practices, etc. It should be noted that in relation to confirmation of the amount of the CFC profit received by the foreign entity the following provision is a general trend. If the Russian Federation does not conclude an international tax treaty with a specific country, then supporting documents must be certified by the competent tax authority of the respective country. In turn, when submitting supporting documents to the Russian tax authorities in a general manner, there is no obligation to notarize or apostille them. At the same time, an important condition in the evolution of accounting for the criterion indicator of profit received by the CFC in determining the tax base and the corresponding tax amount for 2015 and 2016 was the establishment of a threshold value for the tax period of more than 400 thousand euros, and a decrease in the minimum value up to 140 thousand euros in subsequent periods. Moreover, in order to determine the sum criterion, the amount of dividends paid on such a controlled company (distributed profit) is not taken into account. At the same time, if the minimum value of the sum criterion has not been exceeded, information on the amount of profit (loss) received on the CFC must be presented in the income tax declaration.

It should be noted that if the minimum size of threshold values is not exceeded by the CFC, the tax return must be filled in according to the simplified procedure, and in the case of loss, this provision cannot be applied. When identifying the features of the procedure for calculation and payment of the CFC's income, it is important to pay attention to the procedure for such an option when CFCs are registered in offshore jurisdictions.

In this case, using a general approach, the taxpayers either determine the profit received by the CFC on the basis of the financial statements within the same financial year of the company or carry out the calculations based on the provisions of the Tax Code of the Russian Federation. In this case, the rules apply to legal entities operating in the country. Therefore, if such CFCs are registered in offshore jurisdictions and the information on them does not contain data on the submitted statements, in this case, the controlling person is obliged to apply the provisions of the Tax Code of the Russian Federation. Thus, for such cases, there is no right to choose.

It should be noted that, as a general rule, the selected method of calculation and payment of the CFC income involves the actions of the taxpayer, namely: recording in the accounting policy for taxation purposes (for Russian organizations) and application to a specific CFC for at least five subsequent calendar years (tax periods). As a general rule, the accounting policy of the company for taxation purposes should contain an approved list of primary documents, on the basis of which the size of the CFC profit is calculated if they are applicable to the provisions of the Russian tax law and the company does not have financial statements. At the same time, on the practical side of the issue, such regulation of the list seems appropriate: the taxpayer can subsequently remove potential risks in demanding by the fiscal authorities of the documentation that is not used in principle in this CFC.

At the same time, tax legislation also provides for a reduction in the amount of the tax calculated in relation to the income received by the CFC. In these cases, it is subject to reduction in proportion to the share of the controlling person by the amount of the calculated tax amount in relation to:
1) income received (in relation to the Russian and foreign legal field of law);
2) income received of the permanent representative office of the CFC located in the Russian Federation.

The study of the growth rate of the tax base and the calculated amount of tax payable to the budget in relation to the profits received by the CFC to the budget of the Russian Federation was conducted on the basis of statistical data of the Federal Tax Service of Russia for the tax periods 2016-2018 (Fig. 4).
Figure 4. Comparative characteristics of the growth rate of the tax base and the amount of tax payable to the budget in relation to the CFC income payable
Source: The authors' research according to (nalog.ru, 2020)

The analysis of statistical data for the tax periods of 2016-2018 made it possible, based on a comparison of the tax bases for calculation of the CFC tax and tax payable, to determine the actual tax rate in the following limits:
- for the CFCs, the income of which is determined according to financial reporting compiled by their personal law:
  - ✓ 6% for 2016;
  - ✓ 7% for 2017;
  - ✓ 5% for 2018;
- for the CFCs, the income of which is determined by the rules of national law:
  - ✓ 20% for 2016;
  - ✓ 18% for 2016;
  - ✓ 17% for 2016;

A correlation analysis revealed a strongly pronounced linear relationship between the tax base and the tax rates; however, in the case of CFCs, which are primarily subject to national legislation, the correlation coefficient was +0.89, which characterizes the economic trend towards a reduction in financial investments, despite the decrease in the actual tax rate. In turn, for CFCs, whose activities are regulated to a greater extent by foreign legislation, the correlation coefficient amounted to a value of -0.93, which is characterized by a reflection of the greater economic effect of lowering the actual tax rate in the following scenario: a reduction in the tax rate represents more financial injections into the national jurisdiction.

6. Discussion

First of all, it should be noted that, as part of a scientific study, one of the important tasks is to understand the theoretical aspects and practice in the specifics of supranational legal regulation of CFCs' income taxation in the countries of the European Union (Gootjes, 2020). At the same time, for quite a long time, there has been a clear tendency in the legal regulation in the field of taxation in the EU member states aimed at phasing out tax sovereignty within the framework of the united pan-European doctrine and economic community, represented primarily by transnational corporations (Baudot, 2020).

At the same time, at the level of the opinions of individual economists such as Kneller (2014) and Hathikal (2020), the recommendations contained in scientific studies in the form of separate proposals for establishing special tax regimes for certain categories of taxpayers in those EU member states in which the current maximum corporate income tax rates exceed their average values were repeatedly presented. In particular, such states include Austria and Belgium. This circumstance can be considered as a pronounced tax competition regarding the application of direct taxes in the EU member states (Linaa, 2020).

At the same time, the general approach to harmonization in the EU countries relates mainly to indirect taxation (Thanou, 2020). Accordingly, the current direct taxes are incorrectly attributed to them. At the same time, from a legal point of view, the current fact of a particular country's membership in the EU fully contains the obligations to formulate the norms of national tax legislation, including the scope of regulation of corporate taxation in relation to the CFCs (Biggeri, 2017). In this regard, the adoption of a package of regulatory legal acts by the European Commission in 2016 was characterized by a desire to build a unified system of corporate taxation. In this regard, it can be noted that this circumstance is fully similar to the current order of practical experience in building an indirect taxation system, and above all, VAT. In this regard, it can be noted that over the past few years, the pan-European course on tax integration is aimed at:
1) the functioning of a single consolidated corporate tax base (Nakamura, 2018);
2) taking into account the current OECD recommendations regarding the application of the provisions on BEPS (base erosion and profit shifting) (Majumder, 2020), which is also guaranteed by the taxation of the profits of the CFC subject to a number of conditions.

It should be noted that after the formation of a specific Brexit policy, the issues of general tax integration began to be more widely discussed, including the elements of legal emphasis (Perrone, 2020), taking into account the positive adoption of existing rules by the EU member states (Gozubuyuk, 2020). The reason for this policy was a peculiar approach from the UK, which conditionally agreed with the main motive of the BEPS plan, but rejected the general tax integration with the EU member states.

Conclusion

Based on the results of the study, it can be concluded that, in general, the current path for the development of tax legislation in most countries is typical from the perspective of the current legal regulation of CFCs. At least, three directives of the Council of the European Communities (EU Council) should be noted which are currently the legal tools for the legal regulation of the CFCs. First of all, the effect of EU Council Directive 90/435/EEC should be mentioned, which includes provisions that are characteristic of the entire taxation system of parent companies of EU member states and their subsidiaries. At the same time, on the basis of this directive, the tax on dividends for such organizations was canceled. In turn, the practical application of the EU Council Directive 2009/133/EEC, which replaces the previously effective Directive 2003/49/EU, taking into account the existing provisions, is aimed at the transfer of assets and the exchange of shares of companies that are tax residents of several national jurisdictions within the EU. At the same time, in terms of the application of the CFC, the effect of the Council

Directive 2003/49/EC should be mentioned, on the basis of which all processes related to the taxation of interest and royalties paid by associates within the jurisdiction of the EU countries use a direct prohibition on taxation directly in relation to the intragroup calculated amounts of interest and royalties, as well as the payments made on dividends. Meanwhile, the current EU legal doctrine, under the influence of Brexit, in the medium term can influence the adoption of additional directives in the field of corporate taxation, since it is the United Kingdom that remains a key financial center of the EU, where an unprecedented (on the EU scale) amount of the CFCs operate, which in turn provide direct investment in the EU, and therefore make a significant share in the form of foreign direct investment in the EU (Permikin, 2018). Thus, taking into account the circumstances, the following situation may arise in the practice of international taxation: a European subsidiary paying dividends (or interest) to the parent company operating in the UK. The following practical aspect arises: the ability or inability of such a company to refer to existing directives in order to exempt the dividends from taxes. It should be understood that in the case of a positive answer to the question, the problem of double taxation of the amount of dividends received (or interest payments, or royalties) both from the UK in the EU and vice versa under the Brexit conditions arises. This problem is the most vulnerable since the tax period of 2021.

Further, it is important to pay attention to the following fact. Against the background of the unification of tax rules in the EU, which is quite consistent and successful in specific areas, the issue of inconsistency of the rules of CFCs in the national jurisdictions of the EU member states remains unresolved. This fact raises a challenging and quite logical question: if the EU has a common economic and legal space, then how legitimate is the application of the general CFC regime, since taking into account fundamental European economic freedoms, which, in particular, are enshrined in the OECD Model Double Taxation Convention on Income and Capital, the admissibility of the CFC internal rules to various external challenges within the EU is a controversial practical issue. Nevertheless, the state is trying to bridge the current gap in the practical plane of taxation. In particular, in 2015, a special Report "Designing Effective Controlled Foreign Company Rules" was adopted. These rules contain a provision on the need to develop the uniform, unified CFC rules while preserving the freedom of the EU member states to develop their own provisions that take into account national specifics. At the same time, a uniform approach in the field of legal regulation of CFCs in the EU countries is manifested in most of its states on the basis of provisions that define (1) the concept of CFCs, and (2) the controlling person, as well as (3) the procedure for determination and imposition of such CFC income. In the authors' opinion, this approach will contribute to the preservation of the sovereignty of the tax bases.

Abstract. The main objective of this research is to study and develop the strategic intuition indicators of small and medium-sized enterprises (SMEs) in Thailand. The results will serve as a guideline for creating a model to develop the strategic intuition capability of entrepreneurs in Thailand in the future. The research studies relevant literature from empirical data and tests the consistency of a linear structural relationship model by using component analysis techniques. A questionnaire was used to collect data from a sample of entrepreneurs who are SMEs from the database of the Thailand Exporter Directory, the Ministry of Commerce. The results showed that the developed strategic intuition model is in harmony with empirical data, with the strategic intuition variables consisting of three main components: (1) Sensing capabilities, (2) Aggressive thinking capabilities, and (3) Strategic decision capabilities, with a positive value. It was also found that in each component of the measurement model, strategic insight had the same straightness, and the variability of the structural confidence values passed the standard criteria.

Keywords: strategic intuition; intuition indicator; entrepreneurs; SMEs; Thailand

1. Introduction

Nowadays, the road to either success or failure in business operations depend on entrepreneurs' decision-making (Simon, 1997; Robbins, 2003). Hence, in the 21st century, the most successful and innovative entrepreneurial leaders will focus on sustaining superior performance, strategies, and foresight and learn to challenge themselves occasionally (Srichan, Tachaphahapong, & Methakunavudhi, 2016). An entrepreneurial strategy confers a competitive advantage by selecting business solutions that eliminate some weaknesses and plan or correspond procedures for unique benefits and goals (Kouzes & Posner, 2012; Duggan, 2013). Many businesses have grown by leaps and bounds over the past year, as a result of entrepreneurs' abilities and their future predictions. Otherwise known as strategic intuition, this is one type of learning strategy that entrepreneurs use to learn more successfully. Hence, an effective business roadmap will help and develop the strategic intuitions of entrepreneurships in circular business advantages. For these reasons, this study develops strategic intuition indicators by using principal component analysis techniques to verify the dimensionality and structure of variables. The study includes an explanation of the statistical relationship between the smallest variables of latent variables (unobserved variables), referred to as their components. Wiratcha (1999) explained an important concept regarding the structure of principal component analysis, which some variables couldn't objectively identify and measure its physical characteristics. It is known as latent constructs/variables or unobserved variables. Nevertheless, all these details can provide accurate references. However, principal component analysis is part of a statistical–technical process to expose existing latent variables by differences between studying observed variables and analysis of variance. Hopefully, this study of strategic intuition will prove helpful to innovative entrepreneurs. In particular, the developed strategic intuition model can be identified more clearly and positive steps can be taken toward achieving the objectives of entrepreneurs in Thailand. The main objective of this research is to study and develop the strategic intuition indicators of small and medium-sized enterprises (SMEs) in Thailand and facilitate the development of strategic indicators to guide the model to promote the strategic intuition capability of entrepreneurs in the future.

2. Literature Review

2.1 Concepts and theories of developing indicators

Kanchanawassi (2002) stated the dimensional conceptualisations of the process of developing indicators that captured two concepts; 1) Developing indicators by either grouping variables or related components or by consistency with the representative status through a principle of theoretical logic. The next step is to set the priorities of variables or components that follows by developing process indicators to synthesise either variables or indicator components. 2) Developing indicators by analysing the empirical data, and then grouping either variables or related components by using a statistical method for creating indicators. Nowadays, for both these concepts most popular methods and modern trend in research methodology. Wiratcha (1999) suggests that the concept of developing indicators characteristics is similar to the process of studying variables but that each stage of a quality audit is likely to be divided between the different stages of developing indicators. Additionally, good and high-quality of developing indicators should be reliable, valid, capable, consistent, and acceptable (Gibbon, 1996). For the developing indicators' methodology that normally used factor analysis, by using empirical data. All things considered step by step; analysing and grouping variables. Through the developing indicators' concept that can defined in two methods; 1) Developing indicators by using Exploratory Factor Analysis (EFA), which develops the indicators as latent variables. This technique does not either identify the model or engage the support hypothesis. However, the developing indicator technique also has a weak point, in that its analysis of results is ineffective. For this reason, the technique identifies all variables in the model as the result of all components, and the variable error is irrelevant. 2) Developing indicators by using Confirmatory Factor Analysis (CFA), which develops the component analysis by estimating accuracy hypothesis model with theory engagement. This

technique can decrease the negativity and weak point of exploratory factor analysis (Pinyo, 2018). A survey of many international studies provides an overview of a developing indicators' topic, which is developing the indicators from the database and checking the accuracy of the hypothesis model. The developing indicators were created by methodology and empirical analysis that uses the Structural Equation Model (SEM). Meanwhiles, a theory is formalised model that is both consistent and correspondent with empirical data. Also included is the structural equation model, which is an effective tool for estimating the parameters of the developing indicators (Tan, 1992; Ashworth & Harvey, 1994; Joseph & Joseph, 1997).

2.2 Concepts and theories of the strategic intuition

Intuition is a mental process that involves instinctive feeling rather than conscious reasoning and quick decision-making stemming from knowledge-based experience (Miller & Ireland, 2005). From the scientific perspective, the human recognition process consists of five senses. However, the concept of this research is intuition, represented by a sense of foresight arising from one's own instinct. Khatri and Ng (2000) explain intuition as being part of some entirely subconscious level. This level of thinking differs from systematic thinking. This is consistent with Dane and Pratt (2007), who state that the past experiences of leaders are as important as are effectiveness and efficiency in a leadership role. A leaders' relevant experience and background can enable them to identify the critical factors of phenomena. Phaskyud (2012) explains that the capacity of foresight is the part of the vision of a leader, focusing attention on what matters most. A useful vision must be rooted in a leader's past and has gained remarkable for his/her perfect wisdom to explain future scenarios. In addition, Dadds (2008) reports that the processes of categorising and evaluating competitors to understand their strengths and weaknesses are important for business competition in enabling business leaders to determine how their competitors will respond to their next move and process-perspective. Koksat (2007) defines the concept of intuition as the transference of feeling to the surrounding environment and understanding of the basics of new beginnings. Schmidt (1996) identifies intuition as the key point of communication systematic-process and environment. Aujirapongpan and Jutidharabongse (2017), studied the following strategic intuition development concept from Duggan (2013). They found that the intuition development process consists of 4 steps: 1) Learning the successions and examples from history. Entrepreneurs should have former business experience, irrespective of whether it is of success or of failure. These direct or indirect reasonings can be transferred to the next step of business thinking. 2) Creating presence of mind, which is thinking outside the box, associated with concentration and from a new perspective. 3) Reflecting the innate idea and flash of insight. This involves integrating two previous steps to arrive at intuition through concentration. 4) Operating as the resolution. Operating at peak efficiency and being ambitious can drive realistic strategies. Jutidharabongse, Aujirapongpan, and Ritkaew (2020) describe the development of dynamic knowledge management capability and strategic intuition. They find that development of genuine wisdom by systematic knowledge management through conscious mental concentration can lead to the next stage of strategic intuition. The successful development of the skill of intuition is based on the condition of mind whereby past and present states are blended. Thinking creatively and freely allow one to have many and greater perspectives on events (Duggan, 2013). In considering the components in strategic intuition, Aujirapongpan and Jutidharabongse (2017) explain this concept from an eastern perspective related with Buddhist practices (three studies). Three studies consist of morality, concentration, and wisdom. One's mental state and knowledge state are both important for problem-solving. The strategic intuition indicators are represented and summarised in Table 1.

3. Methodology

This study explores the developed strategic intuition indicators of SME entrepreneurs in Thailand through qualitative research by exploratory factor analysis and confirmatory factor analysis. The study uses empirical data and questionnaires and verifies the correspondence model extract information on the associate with SMEs entrepreneurs in Thailand.

3.1 Sample and unit analysis

This research collected and analysed a sample of entrepreneurs in SMEs, in addition to all entrepreneurs that also engage in international knowledge and business and are involved in long-term strategic planning and control for their organisations. The presented assessments are based on reference data from 2,784 companies from the Thailand Exporter Directory, Ministry of Commerce (Updated 31st December 2017). The research sample was collected from 360 SMEs, based on research methodology and Structural Equation Modelling. Optimising balance that the sum of weights across equals the total matched sample size by 20 times of variables in Structural Equation Modelling (SEM) (Wiratchai, 1999). The unit of analysis of the current study is Proportional Stratified Random Sampling for each group of SMEs.

3.2 Research tools and techniques

This study used questionnaire methods as research tools to collect data for examining the relationships between variables. This methodology was adapted from current studies and research theories engaged in phase 1 of qualitative research. This study is set out in two sections: the first is survey questions about the personal information of entrepreneurs. The second is the components in the strategic intuition of entrepreneurs.

3.3 Data collection, analysis, and measurement

To achieve the study's research objectives, the researcher wrote and used a petition letter and questionnaires. Collecting and analysing the survey data for all executives via post mails. 1 month later, which of the following their results. Meanwhile, phone calls were made to identify the correct respondents from the firms. Many questionnaire answers were readily perceived, and some were intensely reacted to rejection. Based on the comprehensive results of the existing questionnaire answers, the researcher checked again to see whether some of the results suited the context of the research methodology. The researcher measured the consistency test of Linear Structural Relationship that is used in the SEM-Analysis technique. Meanwhile, the researcher used the LISREL program to develop empirical benchmarks of comparison that reflected the questionnaires. This included analysing the mean and standard deviations in the statistical data set. The Kaiser–Meyer–Olkin Measure of Sampling Adequacy and Bartlett's Test of Sphericity were used to compare the observed correlation matrix and check for redundancy between the variables that can be summarised with a few numbers of factors by using the Partial Correlation and Identification of the Model. To study on the model configuration parameters, determine how the model runs by specifying the condition analysis. Includes, the Factor Analysis by using EFA and CFA to verify all factors and the consistency of theories. Representing a rational and logical set of relationships exist among all components.

4. Empirical Results and Discussion

4.1 Results

The researcher examined and studied the context of the validity of the measure used in data collection using 342 questionnaires (Aujirapongpan & Hareebin, 2020). The average survey response rate was 31.06% as respondent's submission. However, the survey response rate was confirmed as being enough to create the SEM by the sample size-information answers (See Table 2).

Table 2. Frequency and percentage of the sample size-information answers (n=342)

Information	Status	Frequency	Percentage
Gender	Male	303	88.60
	Female	39	11.40
Age	31 – 40 years old	55	16.08
	41 – 50 years old	129	37.72
	More than 50 years old	158	46.20
Education	Bachelor's degree	35	10.23
	Master's degree	295	86.26
	Doctoral degree	12	3.51
Work experiences	Less than 10 years	15	4.39
	10 – 15 years	42	12.28
	16 – 20 years	135	39.47
	More than 20 years	150	43.86
Position	Vice president / Executive Chief	39	11.40
	Managing director / Assistant managing director	252	73.68
	Chief officer / Manager	51	14.91
Length of business operation	Less than 10 years	50	14.62
	10 – 15 years	187	54.68
	16 – 20 years	97	28.36
	More than 20 years	8	2.34
Total number of staff employed	1 – 50 people	5	1.46
	51 -100 people	70	20.47
	101 – 200 people	267	78.07

The analysis in Table 2 is based on data collected from 342 questionnaires. The results shown in Table 2 indicate that 303 people (86.60%) males are more likely to be vulnerable, compared to only 39 females (11.40%). The table also reveals that, on average, approximately 158 (46%) are more than 50 years old, approximately 129 (37.75%) are less than 50 years old, and approximately 55 (16.08%) are 31–40 years old. A total of 281 (86.26%) of the entrepreneurs have a Master's degree, 35 (10.23%) have a Bachelor's degree, and 12 (3.51%) have a Doctoral degree. A total of 150 (43.86%) of the entrepreneurs have more than 20 years' work experience, 135 (39.47%) have 16–20 years' work experience, 42 (12.28%) have 10–15 years' work experience, and 15 (4.39%) have less than 10 years' work experience. A total of 252 (73.68%) of the sample hold positions as managing directors and assistant managing directors, 51 (14.91%) hold positions as chief officers and managers, and 36 (11.40%) hold positions as vice presidents and chief executives. The table also show that 187 (54.68%) of the business have been in operation for 10–15 years, approximately 97 (28.36%) have been in operation for less than 10 years, approximately 50 (14.62%) have been in operation for 16–20 years, and approximately eight (2.34%) have been in operation for more than 20 years. A total of 267 SMEs (78.07%) have approximately 101–200 staff, 70 (20.47%) have approximately 51–100 staff, and five (1.46%) have approximately 1–50 staff.

In the next step of the study, the researcher analysed the components of EFA in the variables of 15 strategic intuition indicators. Studies has proven that didn't find the indicators less than 0.3. This means that the number of indicators and amount of questions are similar. Testing of the correlation matrix by Bartlett's Test of Sphericity yielded an approximate Chi-Square of 1,740.28, with 105 degrees of freedom, and a P value = 0.000. Significance level was 0.01, and the Kaiser-Meyer-Olkin statistic was 0.587, which means the correlation matrix of the latent variables is not the identity matrix. This study has confirmed that the relationships between variables and factors are enough to create either a component model or a strategic intuition indicators model at the international level. The components of weight indicators are shown in Table 3.

Table 3. component of weight strategic intuition indicators

Strategic intuition indicators	Component of weight		
	3	2	1
V1 Intention and learning from previous experience to guide automatic individual decision-making.	0.848	-0.101	-0.252
V2 Capacity for change and performance in the external environment of exporting business.	0.761	-0.407	-0.089
V3 Integrated customer thinking for better understanding customer needs and wants.	0.738	0.304	0.282
V4 Analysis of the feasibility of future clients' needs.	-0.614	0.304	0.208
V5 Clearly indicated details and trends of future clients' needs.	-0.547	-0.239	0.179
V6 Comparison methodology in former situations for cause finding.	-0.512	-0.070	0.059
V7 Basic of multiple perspectives' analysis for problem solving in organisations.	-0.432	-0.502	-0.005
V8 Adaptation technique of proactive thinking for finding customer needs.	0.023	0.780	-0.206
V9 Data collection technique from many places, which helps in strategic decision planning.	-0.110	-0.619	-0.317
V10 Critical thinking evaluation and using the results for strategic planning.	-0.281	0.501	-0.369
V11 Identification and analysis of the causes of an organisation's problems.	0.037	-0.398	-0.021
V12 Identification of multiple options for operational objectives of organisations.	0.055	0.024	0.615
V13 Optional analysis as the problem-solving guideline.	-0.188	-0.046	0.748
V14 Comparison between different possible options and selection of suitable options.	0.002	0.142	0.731
V15 Evaluated value consideration in significant options and disadvantage evaluation.	0.321	0.083	-0.543

Table 3 shows that the components have Eigenvalues of >1 and cumulative variance of approximately 48.735%. This means that all latent variables can explain the variance of three components (48.735). All components shown contribute significantly to the study (Shown in Table 4).

Table 4. Components of Eigenvalues, percentage of variance, and percentage of cumulative variance in strategic intuition components

Components	Initial Eigenvalues			Extraction Sums of Squared Loading		
	Total	Percentage of variance	Percentage of cumulative variance	Total	Percentage of variance	Percentage of cumulative variance
1	3.440	22.930	22.930	3.440	22.930	22.930
2	2.147	14.310	37.241	2.147	14.310	37.241
3	1.242	11.495	48.735	1.242	11.495	48.735

Table 4 confirms that the results can identify the strategic intuition indicators. All of them can be related with these concepts and theories;

1. Indicator V1–V6 defines respective components of ability to recognise opportunities (Sensing capabilities), or SI1, represented as either intuition capability or seeing opportunity. That leads to evaluated consideration for the imagination situation.

2. Indicator V7–V11 defines respective components of ability for proactive thinking (Aggressive thinking capabilities), or SI2, represented as thinking, previous experience, and the existing situation. The concept focuses on future situations that can respond to external factors.

3. Indicator V12–V15 defines respective components of ability to make decisions proactively (Strategic decision capabilities), or SI3, represented as conditions for making decisions in an organisational vision. Emphasis is placed on future situations related to the effectiveness of business competition.

The reliability of each component was assessed by using Cronbach's Alpha Coefficient (Cronbach, 1990). Each component must have acceptable reliability of Alpha Coefficient for each scale of no less than 0.70. This is an acceptable reliability result (Shown in Table 5).

Table 5. Alpha Coefficient of strategic intuition components

Variables	Components	Alpha Coefficient
Strategic intuition (SI)	Ability to recognise opportunities (SI1)	0.953
	Ability for proactive thinking (SI2)	0.825
	Ability to make decisions proactively (SI3)	0.911

This study applied normal distribution tests using the results of basic statistical analysis, skewness, and kurtosis. The results show a normal distribution of data, meaning that most of the elements in the data set are close to the level of acceptance and are no more than 2.58 (Hair, Black, Babin, & Anderson, 2014). See Table 6.

Table 6. Basic statistical analysis results of strategic intuition components

Components	$\overline{X}$	Comprehension	S.D.	SKEW	KURT
Ability to recognise opportunities (SI1)	3.821	High Level	0.319	0.325	-0.906
Ability for proactive thinking (SI2)	3.831	High Level	0.262	0.185	-0.301
Ability to make decisions proactively (SI3)	3.853	High Level	0.213	-0.075	0.280
Total	3.835	High Level	0.139	0.153	0.011

From Table 6, the variables of strategic intuition (SI) shows that the average level the of variables is high ($\overline{x}$ = 3.835). Meanwhile, the averages of the components of ability to recognise opportunity (SI1), ability for proactive thinking (SI2), and ability to make decisions proactively (SI3) are between 3.821–3.853. The standard deviation is between 0.213–0.319. Following the normal distribution tests of the variables of strategic intuition (SI), which measure by components or three variables; ability to recognise opportunity (SI1), ability for proactive thinking (SI2) and ability to make decisions proactively (SI3). See Table 7.

Table 7. The normal distribution tests

Variables	Skewness	Kurtosis	Normal Distribution
SI	0.153	0.011	√
SI1	0.325	-0.906	√
SI2	0.185	-0.301	√
SI3	-0.075	-0.280	√

The analysis in Table 7 is based on the normal distribution tests. The results indicate that all components or latent variables in three strategic intuitions have skewness of between -0.075–0.325 and kurtosis of between -0.906–0.010. In all these results, skewness is no more than 0.75 (absolute value) and kurtosis is no more than 1.5 (absolute value) based on the normal distribution concept, which results are suitable for CFA (Wiratchai, 1999).

The findings also indicate Construct Validity; this was tested through questions about the latent variables, using the average of the composite score. More than one question was used for the item parcelling to reduce the number of indicators in the structural equation and to increase the consistency of opportunities. This is an acceptance concept for the Structural Equation Analysis Technique. The results of the validity tests of strategic intuition used by the Measurement Model include the CFA using Lisral version 8.72. As the first results did not match the empirical data, the model was further developed and re-tested in question welders by testing and adjusting the Modification Indices (MI). After adjustment of the model, the results indicated that the model matched the empirical data (See Fig.1).

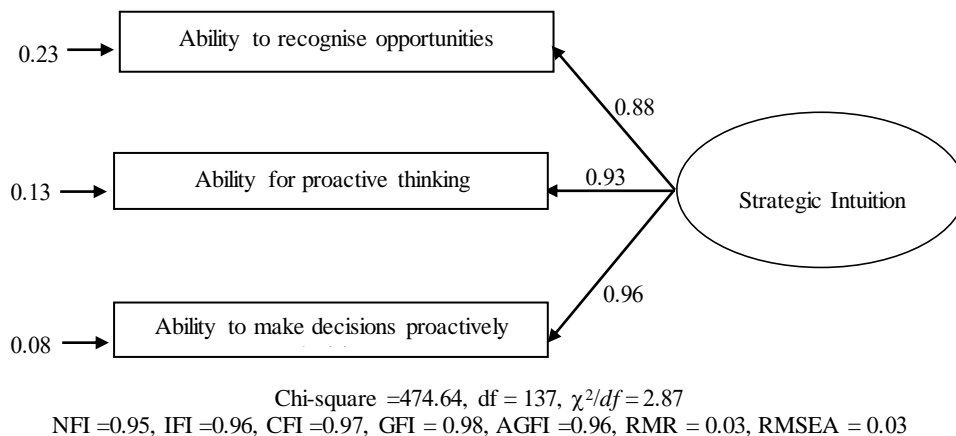
Chi-square =474.64, df = 137, $\chi^2/df = 2.87$
NFI =0.95, IFI =0.96, CFI =0.97, GFI = 0.98, AGFI =0.96, RMR = 0.03, RMSEA = 0.03


Fig. 1 The results of components validity analysis on strategic intuition measurement model (Developed model)

Fig.1, CFA of the strategic intuition measurement model after being further developed and re-tested. The overall results of measurements of the model's fit show that the proportion of Chi-square and degrees of freedom (χ^2/df) are 2.87, which is less than the acceptance criterion of three. More than or equal in 0.90 is the specify indexing. The acceptance criteria for indexes are GFI = 0.98, AGFI = 0.96, NFI = 0.95, IFI = 0.96, and CFI = 0.97. Meanwhiles, if it's less than 0.08 indexing. The acceptance criteria for indexes are RMR = 0.03 and RMSEA = 0.03. This means that the developed strategic intuition model matches the empirical data. In addition, the validity testing on the strategic intuition measurement model was measured by using the Component Fit Measure. The Measurement Model shows the variables of strategic intuition (SI), which consist of Factor Loading (Three components are positive). The component of "ability to recognise opportunities (Factor Loading = 0.88)" fluctuates in quantities deriving from the strategic intuition (77.0%), the component of "ability for proactive thinking (Factor Loading = 0.93) " fluctuates in quantities deriving from the strategic intuition (87.0%), and the component of "ability to make decisions proactively (Factor Loading = 0.96)" fluctuates in quantities deriving from the strategic intuition (92.0%). In addition, each components of strategic intuition model are the Convergent

Validity, because of Construct Reliability: ρc is equal in 0.95. It means, that passed the criteria (> 0.60) and the fluctuation of Construct Reliability: ρv is equal in 0.85 that also passed the criteria (> 0.50) (Hair et al. 2014). See Table 8.

Table 8. The results of convergent validity in the strategic intuition model

Variables	Latent variables	Factor Loading			t	R^2
		B	S.E.	B		
SI	SI1	1.00	-	0.88	-	0.77
	SI2	1.07	0.04	0.93	26.50*	0.87
	SI3	1.15	0.05	0.96	24.01*	0.92
		ρc= 0.95, ρv = 0.85				

*P<0.05

4.2 Discussion

The researcher had developed and studied the indicators, which the concept of developed indicators by Empirical Definition. SEM identified three components of strategic intuition: (1) Sensing capabilities (ability to recognise opportunities), (2) Aggressive capabilities (ability for proactive thinking), and (3) Strategic decision capabilities (ability to make decisions proactively). In addition, SMEs in Thailand have a high level of strategic intuition and a wide variety of capabilities. Strategic decision capabilities are highest, followed by aggressive capabilities and sensing capabilities, respectively. These results match those of Aujirapongpan and Hareebin (2020), Myers (2002), Riqueleme and Watson (2002), Kahneman (2003), and Bradley (2007). The study shows that SMEs in Thailand have the ability to conduct environmental value assessment through experiences and self-management to identify existing problems. This includes Option analysis for problem solving by comparing all possible options. This is based on value consideration and strategic business value creation.

5. Conclusions

The analysis of EFA on strategic intuition variables by 15 indicators that affects to this research. Taking all these things into consideration helps in identifying the sub-components to be the guideline for developed strategic intuition capability through the Manifest Variables. The Manifest Variables consist of three components; (1) ability to recognise opportunities. This is intuitive capability, or seeing opportunities for learning in consideration and evaluation. This concept can create for each imagination situation. (2) ability for proactive thinking. This is thinking capability, which is based on data, previous experiences, and the existing situation. The concept focus on the future situation that can respond to external factors. (3) ability to make decisions proactively. This is the condition for making decisions in an organisational vision. Emphasis is placed on future situations related to the effectiveness of business competition. However, further research is needed to address other variables. Both individual factors and organisational factors, which affect the competitiveness of SMEs, should be added. This is an important, as these affect firms' performance, including how to study the indicators in each component and to build an effective measurement model. The strategic intuition capability of entrepreneurs is directly related to the strategic selection. Furthermore, the strategic selection of operative planning should be matched with organisational vision and missions. Hence, all entrepreneurs need to gain extensive knowledge and experiences to create and develop their strategic intuition capability. This research provides valuable input to further business start-ups and solutions.

SUSTAINABLE MANAGEMENT OF FRESHWATER SWAMP FOREST AS AN ECOTOURISM DESTINATION IN INDONESIA: A SYSTEM DYNAMICS MODELING[*]

Sjaifuddin Sjaifuddin

Department of Science Education, Universitas Sultan Ageng Tirtayasa
Jl. Ciwaru Raya No.25, Cipare, Kec. Serang, Kota Serang, Banten 42117, Indonesia

E-mail: sjaifuddin@untirta.ac.id (corresponding author)

Abstract. As a freshwater swamp forest that still remains in Java, the existence of Rawa Danau as an ecotourism destination is important to be explored, because its utilization is not yet based on sustainable management principles. For this reason, a system dynamics modeling was then made that integrates various factors in the biophysical, social, and economic dimensions to obtain the best alternative for managing the future ecotourism destinations. Management alternatives are designed in three scenarios: deep ecotourism oriented to very strong/strong sustainability; shallow ecotourism oriented to weak sustainability; and mass tourism oriented to very weak sustainability. The results showed that deep ecotourism was the most suitable scenario to be implemented. Through this scenario, the control of several parameters that were successfully carried out during the 10 years of the simulation are as follows: 1) restrain the growth rate of tourist numbers so as not to burden the environment; 2) reforesting almost all forest land converted so that the restoration of forest functions goes well; 3) increase local community income so that the community gets adequate economic benefits; 4) increase environmental investment so that stakeholders benefit economically, ecologically, and socially in an integrated manner; 5) maintaining biodiversity at a high level; 6) maintain swamp water reserves at a very good level; 7) reduce the volume of solid waste so that it does not burden the environment.

Keywords: sustainable management; freshwater swamp forest; ecotourism destination; system dynamics modeling; Rawa Danau

---

1. Introduction

In the last few decades, tourism has developed into one of the fastest growing industry sectors in the world. Globally, in 2020, it is estimated that the number of tourists will grow 3% to 4% (UNWTO, 2020). The rapid growth of the tourism sector has an impact on increasing the income of countries in the world. Travel & tourism accounted for 10.4% (USD 8.8 trillion) of the gross domestic product (GDP) and created 319 million jobs (10% of total employment in 2018) (WTTC, 2020). It cannot be denied anymore that tourism is the most important part of a country's economy. For developed countries, in addition to making a major contribution to the sustainability of economic growth, tourism based on industry excellence also provides minimal environmental impact (Sjaifuddin, 2018). For developing countries, especially if the industrial development is not good, usually the tourism sector still has a large contribution to the state revenue (Akis, 2011). For example, in Bali, Indonesia, tourism is even able to contribute around 60-70% to the local economy, creating broad employment opportunities, and attracting investment both locally and internationally (Chong, 2020). Thus, in general, tourism is considered to have an important role in improving the quality of life (Garau-Vadell et al., 2018).

In addition to providing a positive influence economically, tourism often also presents new problems in other sectors. The main problem that often arises is the negative impact of tourism on various environmental components: biotic, abiotic, social, economic, and cultural (Cianga, 2017; Alipour & Arefipour, 2020). The negative impact is usually closely related to mass tourism. Conventionally, mass tourism is usually associated with unsustainable use of natural resources and intensive land use (Gabarda-Mallorquí et al., 2017). One of the negative impacts of mass tourism is the increasing volume of urban solid waste (Diaz-Farina et al., 2020). For example, more than 75% of waste production in the City of Paralimni (Cyprus) is generated by tourism activities (Zorpas et al., 2015). Another negative impact is the escalation of CO_2 emissions from transportation activities (Cavallaro et al., 2017). Mass tourism contributes 4.4% to global CO_2 emissions and increases an average of 3.2% per year (He et al., 2018). Improved road networks (i.e., trains, highways, airports) to support mass tourism usually have an impact on deforestation; in addition it also encourages the creation of market integration, other factors that have an impact on deforestation (Brandt & Buckley, 2018). In the coastal zone, mass tourism threatens the existence of the beach sand dune ecosystem (Fantinato, 2019). Mass tourism also drives an increase in demand for clean water supply. This condition has a significant impact on water scarcity (Chong, 2020). In various historical objects, mass tourism has a negative impact in the form of mechanical damage and conflicts of use (Drdácký & Drdácký, 2010).

By considering various impacts of mass tourism, the development of a more environmentally friendly tourism concept has now become an alternative. That is why people give great expectations to ecotourism, because mass tourism always presents a conflict of interest between economic development and ecological conservation (Hsu, 2019). Ecotourism as an alternative tourism concept becomes very interesting because it is considered to provide great benefits economically, socially, and environmentally (Wondirad et al., 2020). According to the International Ecotourism Society (TIES, 2015), ecotourism is defined as "responsible travel to natural areas that conserves the environment, sustains the well-being of the local people, and involves interpretation and education". The concept leads to the fulfillment of 5 ecotourism principles: environmental conservation, community participation, cultural preservation, local community empowerment, and economic benefits (Cobbinah, 2015). As a component of the green economy, ecotourism is a strategy to achieve a balance between economic and ecological interests (Anup et al., 2015), while community participation is considered as the best alternative compared to the social and environmental impacts caused by mass tourism (Southgate, 2006). The impact of ecotourism on local communities is usually identified through the economic, psychological, social, and political empowerment framework (Scheyvens & Scheyvens, 2015).

Ecotourism is a complex and dynamic system that involves various variables: biophysical, social, and economic. In the system, these variables interact with and depend on each other, but it also interacts complexly with other variables outside the system (Aliani et al., 2018). Complex systems also have complex problems, and only using the right methodology can be solved (Jere Jakulin, 2017). System dynamics is a methodology used to analyze complex systems through the development of representative models that reflect actual conditions (Sjaifuddin et al., 2019).

Rawa Danau is a tropical lowland swamp forest located in Serang Regency, 101 km from Jakarta, Indonesia. Rawa Danau is an ancient Volcano caldera of around 2.500 hectares, located at an elevation of 100 m above sea level (van Der Kaars et al., 2001). Ecologically, Rawa Danau is very important because it is the only tropical lowland swamp left in Java. Economically, the important role of Rawa Danau lies in its large potential as a supplier of raw water for industrial and urban areas in Serang Regency and Cilegon City (Priyanto & Titiresmi, 2006). As an ecotourism destination, Rawa Danau has a high attraction because it has beautiful panoramas and is a habitat for various species of flora and fauna. Rawa Danau is also often used as an object of study relating to the theme of ecology, geology, biology, and the environment by researchers from various universities/research institutions both locally and internationally. Nevertheless, the existence of Rawa Danau is also faced with various challenges, including the shrinking of forest area due to land conversion; decreased water storage capacity due to sedimentation processes as well as the lack of successful conservation efforts that have an impact on the overall decline in environmental quality. Considering the various conditions above, this research is important to be carried out in order to develop a model of sustainable management of Rawa Danau. The model built will involve various biophysical, social, and economic variables and be simulated through several ecotourism zone management scenarios. For this purpose, a system dynamics approach is used to provide alternative solutions to comprehensive problem solving.

2. Literature Review

2.1. Sustainable Development of Ecotourism

According to the World Commission on Environment and Development (WCED) Report, the concept of sustainable development is identified from 3 main dimensions: social, economic, and environmental sustainability (Secundo et al., 2020). This concept is increasingly gaining worldwide attention after the United Nations adopted a global action plan for sustainable development, which contains 17 sustainable development goals (SDGs) with 169 targets (van der Waal & Thijssens, 2020). The SDGs are a series of 17 large goals that articulate the outcomes of sustainable development (Ike et al., 2019). One of the key proposals regarding the most effective mechanism for achieving this ambitious agenda in 2030 is to focus on humanitarian-development-peace nexus (Howe, 2019). The declaration of 2017 as the International Year of Sustainable Tourism for Development by UNWTO has encouraged various related sectors (including tourism) to formulate the best strategy for achieving SDGs. According to Siakwah et al. (2019), the strategy was formulated based on the close link between tourism and SDGs (Table 1). Tourism bridges the achievement of SDGs 1, SDGs 13, and SDGs 15 through pro-poor tourism, volunteer tourism, and ecotourism. Community empowerment programs that are packaged through pro-poor tourism policies are proven to be able to provide economic benefits for the poor in rural areas (Torabi et al., 2019). Volunteer tourism in Tortuguero National Park Costa Rica, Mon Repos Australia, and Ubatuba Brazil is considered to have succeeded in creating broader employment opportunities for local people (Liu & Leung, 2019). Agritourism strengthens the linkages between tourism and agriculture through the development of sustainability principles (Addinsall et al., 2017). Ecotourism is one of the mechanisms needed to strengthen adaptive capacity in order to face the challenges of the current and future climate change (Jamaliah & Powell, 2018). Today ecotourism is growing rapidly in areas with high biodiversity because of its potential to achieve economic benefits and ecological conservation (Brandt & Buckley, 2018). Tourism also bridges the achievement of SDGs 6, SDGs 7, and SDGs 12 through alternative tourism and responsible tourism. Alternative tourism is

considered as an efficient mechanism for overcoming various current crises (Papageorgiou & Lytras, 2015). Through a platform of restaurant food surplus, responsible tourism supports the consistent implementation of responsible consumption (*http://ertr.tamu.edu*, 2019). In a conservation perspective, ecotourism is considered as an incentive-based management intervention. This mechanism is always associated with the institutional intervention, spatial restrictions in the ecotourism zone, economic benefits obtained by local communities, and community-oriented monitoring systems (Brandt & Buckley, 2018).

In many developing countries, ecotourism plays an important role as a source of income for local communities and reduces dependence on forests, empowering people through participation, increased access to information, strengthening organizational capacity, minimize the environmental impact, and contribute to conservation through reforestation and habitat restoration (Ma et al., 2019; Das & Chatterjee, 2015). For example, shark watching is an ecotourism industry that is developing rapidly in Mexico, annual gross income from this activity is estimated to reach USD 12.4 million with more than 15 species of sharks successfully conserved (Cisneros-Montemayor et al., 2019). Shark ecotourism in Donsol, Philippines is able to create more than 300 jobs and offer more than 200 seasonal jobs for local fishermen so as to reduce poverty (Gallagher & Hammerschlag, 2011). Bird watching (avitourism) has become a very popular hobby in South Africa, able to provide income of up to USD 362 per month to local communities, and is considered as a cost-effective way to create jobs, carry out conservation efforts, and develop human resources (Biggsa et al., 2011). Turtle watching at Mon Repos Conservation Park, Queensland, Australia is considered very important in promoting environmental education and promoting turtle conservation efforts (Tisdell & Wilson, 2005). Wildlife ecotourism in Manaus, Brazil has now changed the habits of local communities from unsustainable activities to more sustainable community-based activities, increasing forest conservation, and reducing poverty (D'Cruze et al., 2017).

Table 1. Linking SDGs and tourism

SDGs	Possible tourism to attain SDGs
No poverty	pro-poor tourism, volunteer tourism
Zero hunger	agritourism
Good health and well-being	health tourism
Quality education	tourism in-house training courses and skills development of local communities
Gender equality	inclusive tourism
Clean water and sanitation	responsible tourism
Affordable and clean energy	alternative tourism
Decent work and economic growth	local economic development through tourism
Industry, innovation and infrastructure	tourism super-structure
Reduced inequalities	inbound and outbound tourism, inclusive tourism, pro-poor tourism
Sustainable cities and communities	urban tourism, community-based tourism, inclusive tourism
Responsible consumption and production	responsible tourism, green tourism
Climate action	ecotourism
Life below water	aquatourism
Life on land	sustainable tourism, ecotourism
Peace, justice and strong institutions	inclusive tourism, peace through tourism, justice tourism
Partnerships for the goals	justice tourism, collaborative community-based tourism

(Siakwah et al., 2019)

2.2. Threat to Freshwater Swamp Forest

Freshwater swamp forests (FSF) throughout the world are now facing a very serious threat. Various natural and anthropogenic factors are often a threat to FSF and have an impact on decreasing ecological function (Baustian et al., 2018). These natural factors are usually natural disasters, while the anthropogenic factors are overharvesting, incorrect harvesting techniques, conversion to agricultural land, and land burning (Omagor, 1999). Forest degradation is one of the trigger factors for land fires during the dry season (Dwomoh et al., 2019). The excessive

utilization of FSF will be very detrimental especially for flora and fauna that are sensitive to the fluctuations in environmental factors (Sun et al., 2016). FSF is a zone rich in biodiversity and provides a variety of ecosystem services: carbon storage, water sources, germplasm sources, and food sources (Igu & Marchant, 2017). In addition to responding to environmental changes, biodiversity is also a predictor of various ecosystem functions that are important for maintaining human well-being (Mori et al., 2017). FSF is part of the tropical rain forest and has an important contribution as climate change modulators. As a carbon storage zone, the FSF in the Niger Delta, for example, is capable of storing carbon on average 228.28 ton/hectare, a large storage capacity (Igu & Marchant, 2016). The ability to store carbon by the FSF depends on: 1) the ability of flora to absorb carbon from the atmosphere; 2) the material cycle flowing from living biota to dead biota; 3) subsequent deposition and storage processes in the earth (Harrison, 2013).

Changes in FSF biodiversity are mainly caused by 2 important factors: natural and anthropogenic drivers of change (Fig. 1). Both of these factors give effect to landscape modification in the form of hydrological changes, forest degradation, and forest regeneration. The dashed line in the figure means that the FSF is resistant to the invasion of new species, so landscape modification is a more influential factor in biodiversity changes. Landscape modification will cause population change through mechanisms: food resource changes, dispersal constraints, and behavior changes. Meanwhile population change will form mutually influencing relationships with community change and species interaction. On the other hand, overharvesting is one of the important anthropogenic factors that will directly affect population change.
Fig. 1. Effects of natural and athropogenic drivers of change on the biodiversity of FSF (Harrison, 2013).

2.3. System Dynamics

System dynamics (SD) was first introduced in the 1950s by Forrester (Yu et al., 2019). Forrester developed a modeling and illustrated how a policy can affect the stability of industrial systems (Cesar et al., 2020). SD is a sophisticated methodology used to represent complex feedback structures (Teng et al., 2018) so it is very useful to understand cross-disciplinary issues (Tan et al., 2018). SD modeling is characterized by the existence of non-linear relationships and feedback between components in a system and is very suitable to be used to model complex socioeconomic phenomena (Wit et al., 2018). Sustainable management of ecotourism zone has characteristics that are interdisciplinary, dynamics, and non-linear so that it will be very suitable if the model uses

SD. As an aspect of system theory, SD enables the modeller to understand the nonlinearities of the system through structural modeling including circular feedback or time delayed relationships (Daneshzand et al., 2019). The use of the SD methodology is based on three main principles: 1) the development of model structure that determines the system behavior, 2) the involvement of soft variables in the model structure, 3) the understanding of mental models that produce significant leverage (Saavedra M. et al., 2018). Utilization of SD has several advantages, including: (1) visualizing the causal relationship between variables, (2) understanding the impact of delays on the system, and (3) understand the system's response to several different scenarios (Zapata et al., 2019). The researchers used SD to develop policies suitable for problem solving in various dimensions of ecotourism. To simulate a low-carbon ecotourism activity, He et al. (2018) has created a system dynamics design that involves ecotourism activities, carbon waste, and ecology using a case study in Western China. To improve coastal ecosystem management, You et al. (2018) has conducted a simulation of landscape changes using several management scenarios and case studies in Shinduri coastal zone, South Korea. Pizzitutti et al. (2017) uses SD as a decision-support system to provide recommendations to policy makers in managing the Galapagos Islands as an integrated system. Some other researchers who use SD simulations in the field of ecotourism include Lu et al. (2019) who evaluate the effect of socio-economic factors on ecological security systems of coastal tourism cities, Tan et al. (2018) modeling coastal zone management for sustainable tourism, Xu & Dai (2012) explores the policies of a world inheritance village to support sustainable tourism.

3. Method

Tourism is a goal-oriented soft system, built by integrated components e.g. tourists, demand, supply, information, as well as social, material, and financial relations between the existing subsystems (Jere Jakulin, 2017). This study uses SD as a robust methodology to explore long-term ecotourism development policies (Xu & Dai, 2012). SD provides answers to the 'what-if' question through a feedback loop that is built between variables in the system (Sukholthaman & Sharp, 2016). The SD concept is presented simply through graphs and basic formulas and does not use complicated mathematical formulas (El-Sefy et al., 2019). SD methodology is used through the steps of modeling and qualitative methods as follows (Luna-Reyes & Andersen, 2003): 1) conceptualization, consists of 2 steps: problem definition and system conceptualization. In this research, the methods used to identify problems and describe the dynamic hypotheses are interviews and content analysis; 2) model formulation. In this research, the methods used to obtain parameters and policies are interviews and content analysis; while to construct the model formulation is grounded theory; 3) testing, consists of 2 steps: analysis of model behavior and model evaluation. In this research, the method used to justify the structure of the model is expert judgment; 4) implementation, consists of 2 steps: policy analysis and model use. At the implementation stage, the method used to test the policies is experimental approach; while to generate discussion among stakeholders is focus group. This research is only carried out until the 3rd stage.

SD has a set of qualitative tools that are used to analyze various dynamic processes, e.g., causal loop diagram (CLD) and flow diagram (FD) (Honti et al., 2019). CLD is a structure that functions to describe the feedback relationship between variables qualitatively (Moeis et al., 2020). In CLD there are two types of loops: reinforcing loop (R) and balancing loop (B) (Fig. 2 (a)). A strengthening relationship (R) will occur if X increases, then Y also increases; an increase in Y will cause an increase in X again. A balancing relationship (B) will occur if Y increases, then Z also increases; increasing Z will decrease Y (Sjaifuddin, 2020). After the CLD has been formed, an FD (Figure 2 (b)) is built. FD is a dynamic model structure built by several components: levels, rates, and auxiliaries (Walrave & Raven, 2016). In the FD, information accumulation in the system is centered on the *levels (stocks)*; the rate of change in the volume of information is represented by the *rates (flows)*; while intermediate variables that contain various calculations involving other variables are shown by *auxiliaries*. There are two other components in FD: *constants* and *connectors*. Constants are fixed values that affect certain variables, while connectors show links between components in the model.
Fig. 2. Simple causal loop diagram (a) and flow diagram (b)

4. Result and Discussion

4.1. Causal Loop Diagram

CLD on sustainable management of freshwater swamp forest as an ecotourism destination in Indonesia is presented in Fig. 3. This CLD has 3R and 2B. R1 shows a mutually reinforcing relationship between environmental investment and local community income. The greater the environmental investment, the intensity of local community empowerment will be higher; this condition drives the increasing local community income. Conversely, a higher local community income will encourage more intensive conservation efforts; this condition drives the greater environmental investment. R2 shows the mutually reinforcing relationship between environmental investment and community independence. The greater the environmental investment, the intensity of local community empowerment will be higher; this condition then drives higher access to resources, so that the impact on community independence is also higher. Conversely, a higher community independence will encourage greater environmental investment. R3 shows the mutually reinforcing relationship between environmental investment and conservation efforts. The greater the environmental investment, the higher the conservation efforts. Conversely, the higher the conservation efforts, the greater the environmental investment.

Fig. 3. CLD on sustainable management of freshwater swamp forest as an ecotourism destination in Indonesia

B1 shows a mutually balancing relationship between tourists and waste management. The greater the number of tourists, the greater the tourism revenue; this condition then encourages greater environmental investment, which will be used for more intensive waste management. Conversely, the higher intensity of waste management will cause a lower volume of solid waste; this condition will encourage a greater number of tourists. B2 shows a mutually balancing relationship between tourists and biodiversity. The greater number of tourists will have a greater environmental impact; this will lead to lower biodiversity. Conversely, low biodiversity will cause a decreasing number of tourists.

4.2. Flow Diagram

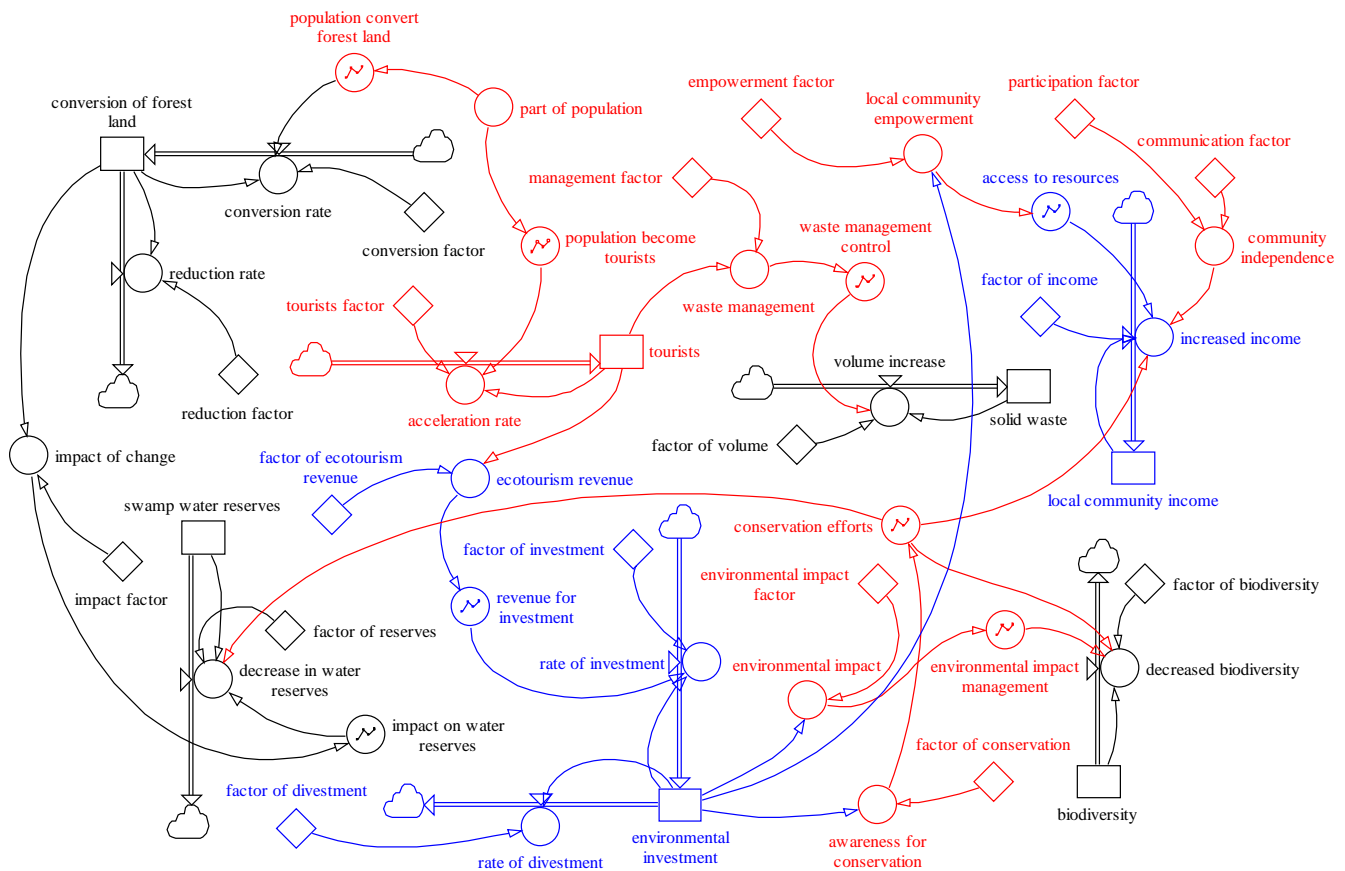
Flow diagrams are presented in Fig. 4 is built based on the CLD in Fig. 3, and named Freshwater swamp forest model (FSFM). FSFM has 3 sub-models: social sub-model (red), economic sub-model (blue), and biophysical sub-model (black). The social sub-model is a main model that has 1 level: 'tourists' and 2 auxiliaries: 'local community empowerment' and 'environmental impact management'. The economic sub-model is a co-model that has 2 levels: 'local community income' and 'environmental investment'. The biophysical sub-model is a co-model that has 4 levels: 'conversion of forest land', 'swamp water reserves', 'solid waste', and 'biodiversity'.


Fig. 4. Freshwater swamp forest model (FSFM)

'Tourists'

Based on Fig. 4, 'tourists' is a stock with an initial value of 12.584 people. 'Tourists' increase through the 'acceleration rate' which functions as a flow that has the equation: tourists*'tourists factor'*'population become tourists'. The graph function 'population become tourists' has an equation: GRAPHCURVE

(population;0;0,1;{0,127;0,17;0,22;0,3;0,34;0,39;0,51;0,74;0,827;0,84//Min:0;Max:1//}). As a constant, 'tourists factor' has a value of 0.15 1 / year. 'Part of population' is an auxiliary which has a value of 2. 'Population convert forest land' is a graph function that has an equation: GRAPHCURVE (population; 0;0,1;{0,32;0,36;0,367;0,37; 0,387;0,467;0,65;0,807;0,87;0,89//Min:0;Max:1//}). As an auxiliary, 'waste management' has an equation: tourists*'management factor'. 'Waste management control' is a graph function that has an equation: GRAPHCURVE('waste management';0;0,1;{0,52;0,307;0,167;0,11;0,1;0,19;0,33;0,45;0,49;0,4//Min:0;Max:1//}). As a constant, 'management factor' has a value of 1.4 1 / people. All values and equations related to 'tourists' are shown in Table 2.

Table 2. Values and equations related to 'tourists'

Components	Values	Equations
tourists (stock)	12584 people	
acceleration rate (flow)		tourists*'tourists factor'*'population become tourists'
tourists factor (constant)	0,15 1/year	
population become tourists (graph function)		GRAPHCURVE(population;0;0,1;{0,127;0,17;0,22;0,3;0,34;0,39; 0,51;0,74;0,827;0,84//Min:0;Max:1//})
part of population (auxiliary)	0,2	
population convert forest land (graph function)		GRAPHCURVE(population;0;0,1;{0,32;0,36;0,367;0,37;0,387; 0,467;0,65;0,807;0,87;0,89//Min:0;Max:1//})

'Local community empowerment'

Fig. 4 shows that 'local community empowerment' is an auxiliary with an equation: 'empowerment factor'*'environmental investment'. 'Community independence' is also an auxiliary that has an equation: 'participation factor' * 'communication factor'. As a constant, 'communication factor' has a value of 5.1 1 / people; 'participation factor' is 0.05 people; while the 'empowerment factor' is 0.1 1 / percent. All values and equations related to 'local community empowerment' are shown in Table 3.

Table 3. Values and equations related to 'local community empowerment'

'Environmental impact management'

According to Fig. 4, 'environmental impact management' is a graph function that has an equation: GRAPHCURVE('environmental impact';0;0,1;{0,15;0,22;0,287;0,34;0,38;0,407;0,53;0,66;0,71;0,66//Min:0;Max: 1//}). 'Environmental impact' is an auxiliary that has an equation: 'environmental investment'*'environmental impact factor'. 'Awareness for conservation' is also an auxiliary with an equation: 'environmental investment'*'factor of conservation'. The 'conservation efforts' is a graph function with an equation: GRAPHCURVE('awareness for conservation';0; 0,1;{0,207;0,227;0,22;0,207;0,19;0,267;0,467;0,77;0,84;0,847// Min:0;Max:1//}). As a constant, 'environmental impact factor' has a value of 0.00000002 1 / percent; while the 'factor of conservation' is 0.1 1 / percent. All values and equations related to 'environmental impact management' are shown in Table 4.

'Local community income'

Based on Fig. 4, 'local community income' is a stock with an initial value of 3,5 million Rupiah. 'Local community income' increases through 'increased income', a flow that has an equation: 'community independence'*'access to resources'*'conservation efforts'*'local community income'*'factor of income'. 'Access to resources' is a graph function with an equation: GRAPHCURVE('local community empowerment'; 0;0,1;{0,91;0,287;0,23;0,24;0,28;0,45; 0,53;0,607;0,69;0,71//Min:0;Max:1//}). As a constant, 'factor of income' has a value of 1,11 1/year**.** All values and equations related to 'local community income' are shown in Table 5.

factor of income (constant)	1,11 1/year	

'Environmental investment'

Based on Fig. 4, 'environmental investment' is a stock with an initial value of 0,2 percent. 'Environmental investment' increases through 'rate of investment', a flow that has an equation: 'revenue for investment'*'environmental investment'*'factor of investment'. 'Environmental investment' also decreases through 'rate of divestment', a flow that has an equation: 'environmental investment'*'factor of divestment'. As a constant, 'factor of investment' has a value of 0,7 1/year; while the 'factor of divestment' is 0,1 1/year**.** 'Revenue for investment' is a graph function with an equation: GRAPHCURVE('ecotourism revenue' ;0;0,1;{0,1;0,2;0,2;0,227;0,28;0,45;0,76;0,88;0,9;0,9//Min:0;Max:1//}). 'Ecotourism revenue' is an auxiliary with an equation: ecotourists*'factor of ecotourism revenue'. As a constant, 'factor of ecotourism revenue' has a value of 0,0006 1/people. All values and equations related to 'environmental investment' are shown in Table 6.

'Conversion of forest land'

According to Fig. 4, 'conversion of forest land' is a stock with an initial value of 8,57 hectares. This stock increases through 'conversion rate', a flow that has an equation: 'population convert forest land'*'conversion of forest land'*'conversion factor'. This stock decreases through 'reduction rate', a flow that has an equation: 'conversion of forest land'*'reduction factor'. As a constant, 'reduction factor' has a value of 0,3 1/year**;** while the 'conversion factor' is 0,001 1/year, and 'impact factor' is 0,2 1/hectare. 'Impact of change' is an auxiliary with an

equation: 'conversion of forest land'*'impact factor'. All values and equations related to 'conversion of forest land' are shown in Table 7.

'Swamp water reserves'

Fig. 4 shows that 'swamp water reserves' is a stock with an initial value of 500 million m^3 (expert estimates). This stock decreases through 'decrease in water reserves', a flow that has an equation: 'impact on water reserves'*'conservation efforts'*'swamp water reserves'*'factor of reserves'. 'Impact on water reserves' is a graph function with an equation: GRAPHCURVE('impact of change';0;0,1;{0,147;0,4;0,547;0,63;0,727;0,78;0,81; 0,82;0,847;0,85//Min:0;Max:1//}). As a constant, 'factor of reserves' has a value of 0,000001 1/year. All values and equations related to 'swamp water reserves' are shown in Table 8.

Table 8. Values and equations related to 'swamp water reserves'

'Solid waste'

Based on Fig.4, it is known that 'solid waste' is a stock with an initial value of 62.986 kilograms. This stock increases through 'volume increase', a flow that has an equation: 'waste management control'*'solid waste'*'factor of volume'. As a constant, 'factor of volume' has a value of 0,00003 1/year. All values and equations related to 'solid waste' are shown in Table 9.

'Biodiversity'

According to Fig. 4, 'biodiversity' is a stock with an initial value of 95 percent (expert estimates). This stock decreases through 'decreased biodiversity', a flow that has an equation: 'conservation efforts'*'environmental impact management'*biodiversity*'factor of biodiversity'. As a constant, 'factor of biodiversity' has a value of 0,01 1/year. All values and equations related to 'biodiversity' are shown in Table 10.

factor of biodiversity (constant)	0,01 1/year	

4.3. Model simulation

A model simulation is performed to find out the system behavior. By using the euler method (fixed step) at the 1st order, the simulation starts in 2020 until 2030. In this research, the simulation uses 3 scenarios of ecotourism management: 1) deep ecotourism which is oriented towards very strong/strong sustainability, 2) shallow ecotourism oriented to weak sustainability, and 3) mass tourism which is oriented towards very weak sustainability (Acott et al., 1998). There are several assumptions used in the simulation: 1) stable and controlled biophysical environmental conditions (e.g., no disaster occurs), 2) consistent tourism policies, 3) maintaining political and security stability.

The growth of tourists during the 10-year simulation is shown in Fig. 5(a). In the mass tourism scenario, the number of tourists grows exponentially, consequently at the end of the simulation period the number of tourists increased by more than 240% (from 12,584 peoples to 42,853 people). In the shallow ecotourism scenario, the number of tourists increased by 103.3% (from 12,584 people to 25,587 people), while in the deep ecotourism scenario, the number of tourists increased by 38.4% (from 12,584 people to 17,411 people). The large number of tourists will increase the consumption of tourism resources and produce a large volume of waste, because mass tourism greatly exploits natural resources and the environment (Cianga, 2017). In addition, it also becomes a heavy social burden due to increased crime, prostitution, and other social problems (Das & Chatterjee, 2015). Mass tourism in Bali, for example, has had a significant impact: 1) a big burden on waste management, 2) traffic congestion, 3) cultural dilution, 4) tourist misbehaviour (Chong, 2020). In the shallow ecotourism scenario, the number of tourists increased by 103.3% (from 12,584 people to 25,587 people). This increase is considered still quite large and has the potential to burden the environment. In the deep ecotourism scenario, the number of tourists increased by 38.4% (from 12,584 people to 17,411 people). This condition is considered as a fairly logical growth because it is not too high so it does not burden the environment.

| (a) | (b) |
Fig. 5. Growth patterns of tourist numbers (a) and conversion of forest land (b) according to 3 scenarios of ecotourism management

Decreased area of converted forest land during the 10-year simulation is shown in Figure 5(b). In the deep ecotourism scenario, almost all converted forest land (97.2%) has been successfully reforested (from 8.57 hectares in 2020 remaining 0.24 hectare in 2030). This condition shows that the deep ecotourism scenario has successfully restored forest functions well. In the mass tourism scenario, the area of converted forest land only decreased by 21.4% (from 8.57 hectares in 2020 to 6.74 hectares in 2030); while in the shallow tourism scenario, the area of converted forest land decreased by 55.3% (from 8.57 hectares in 2020 to 3.83 hectares in 2030). This condition shows that the two scenarios have not been able to reforest converted land. In relation to climate change mitigation, maintaining forest functions is very important. Research by Suwarno et al. (2018) shows that forest conversion moratorium in West Kotawaringin and Kapuas Regency (Indonesia) is able to reduce the potential of CO_2 emissions by 15%-23%. In another aspect, forest land conversion will also affect the number and composition of litterfall. This condition will certainly affect the content of organic matter and soil nutrient cycles which will then have an impact on soil microbial diversity (Yu et al., 2012). Deforestation also results in lower soil quality, for example, it was demonstrated by decreasing levels of organic carbon and microbial biomass carbon (Rasouli-Sadaghiani et al., 2018).

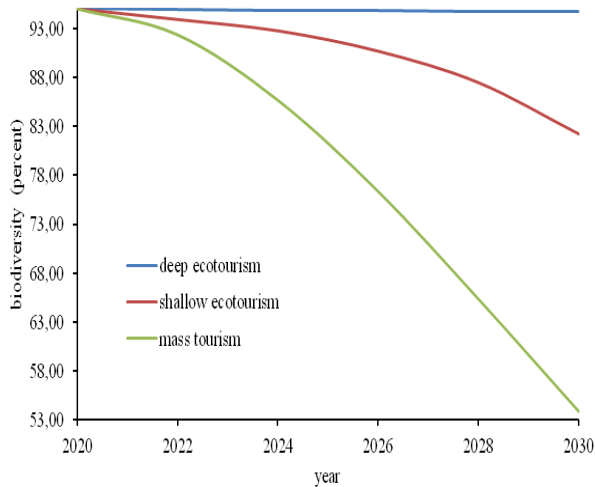
The growth of local community income during the 10-year simulation is shown in Fig. 6(a). In the deep ecotourism scenario, there was a 28.6% growth in local community income (from Rp. 3,500,000 in 2020 to Rp. 4,500,522 in 2030). In the shallow ecotourism scenario, the growth of local community income is only 16.8% (from Rp. 3,500,000 in 2020 to Rp. 4,089,368 in 2030); while in the mass tourism scenario, there was a very significant decrease in local community income: 49.3% (from Rp. 3,500,000 in 2020 to only Rp. 1,775,644 in 2030). This condition shows that the deep ecotourism scenario is the best alternative for increasing local community income. This is in line with the principle of ecotourism that develops in areas with high biodiversity but is still able to achieve economic benefits and ecological conservation (Brandt & Buckley, 2018). Ecotourism in this region is still able to maintain traditional values, create jobs for local people, and provide income for people who were previously unemployed (Scheyvens & Scheyvens, 2015). Declining local community income in the mass tourism scenario is possible because almost all dimensions of mass tourism are controlled by large capital owners, so that the local community is marginalized.

(a)   (b)
Fig. 6. Growth patterns of local community income (a) and environmental investment (b) according to 3 scenarios of ecotourism management

Growth in environmental investment during the 10-year simulation is shown in Figure 6 (b). In the deep ecotourism scenario, there is an environmental investment growth of 2,745% (from 0.2% in 2020 to 5.69% in 2030). In the shallow ecotourism scenario there is an 830% growth (from 0.2% in 2020 to 1.86% in 2030); while in the mass tourism scenario 100% growth occurs (from 0.2% in 2020 to 0.4% in 2030). This condition shows that the deep ecotourism scenario is the best alternative for environmental investment growth. A well-grown environmental investment will trigger an increase in environmental performance. Environmental performance is an effective solution to reduce problems due to over-utilization of resources (Jin-Fang et al., 2020). Environmental investment implemented in the service sector greatly impacts on reducing costs through more efficient use of resources such as energy and water. Environmental investment has now become the choice because with only a small investment, measurable economic benefits will soon be obtained (Bagur-Femenías et al., 2015).

The decline in biodiversity during the 10-year simulation is shown in Figure 7 (a). In the deep ecotourism scenario, there is a relatively small reduction in biodiversity (0.33%) (from 95.0% in 2020 to 94.69% in 2030). In the shallow ecotourism scenario there was a reduction of 13.44% (from 95.0% in 2020 to 82.23% in 2030); while in the mass tourism scenario there was a reduction of 41.11% (from 95.0% in 2020 to 53.89% in 2030). This condition shows that the deep ecotourism scenario is the best alternative to maintain biodiversity. Biodiversity is a source of inspiration and recreation, maintaining the availability of water, producing oxygen, maintaining climate stability, as a source of food, and a source of genetic material that is very important for agriculture and industry (Slootweg, 2005). Throughout the history of civilization, humans have over exploited the nature (including biodiversity). To avoid the threat of mass extinctions, one important strategy is to limit human behavior so that it remains within the tolerance limits of the earth's ecosystems (Raven & Wackernagel, 2020).

The decrease of swamp water reserves during the 10-year simulation is shown in Figure 7(b). In the deep ecotourism scenario, there is a relatively small decrease in swamp water reserves (0,0001%) (from 500 million m^3 in 2020 to 499.9 million m^3 in 2030). In the shallow ecotourism scenario there is a decrease of 19.5% (from 500 million m^3 in 2020 to 402.7 million m^3 in 2030); while in the mass tourism scenario there was a decrease of 62.1% (from 500 million m^3 in 2020 to 189.4 million m^3 in 2030). This condition shows that the deep ecotourism scenario is the best alternative to maintain swamp water reserves. Rawa Danau FSF must be maintained so as not to be converted into agricultural land, settlements or other uses. The research of Peter et al. (2018) shows that forest land conversion has very serious implications on the ability of forests to maintain water resources. Water

availability is a crucial factor because billions of people worldwide currently live in water insecurity conditions (Stoler et al., 2020). To get clean water, people have to pay a high price, even disproportionately compared to household income.


(a)
(b)
(c)

Fig. 7. Growth patterns of biodiversity (a), swamp water reserves (b), and volume of solid waste (c) according to 3 scenarios of ecotourism management

The decrease in the volume of solid waste during the 10-year simulation is shown in Figure 7(c). In the deep ecotourism scenario, there is a significant decrease in the volume of solid waste (99.9%) (from 62,986 kilograms in 2020 to 0.08 kilograms in 2030). In the shallow ecotourism scenario, there was a decrease of 85.8% (from 62,986 kilograms in 2020 to 8,926.47 kilograms in 2030). In the mass tourism scenario, the volume of solid waste actually increased by 64.6% (from 62,986 kilograms in 2020 to 103,682.72 kilograms in 2030). This condition shows that the deep ecotourism scenario is the best alternative to reduce the volume of solid waste. Mismanagement of solid waste has a negative impact on the environment and health, reducing productivity and economic growth (Serge Kubanza & Simatele, 2020). For this reason, solid waste management must be carried

out effectively and institutionalized by involving the government, private sector and community participation. Effective management of solid waste will involve all of these components with several principles: 1) understanding of the factors driving the emergence of solid waste, 2) the seriousness of stakeholders in preventing and reducing solid waste, 3) understanding the determinants of successful management (Filimonau & Tochukwu, 2020).

4.4. Model Validation

The ability of the model to describe the real state can be determined through model validation. In this study the construction validity test is used, aiming to show that the structure of the model being constructed is logical. The simulation shows that the number of tourists in the mass tourism scenario increases exponentially (Fig.5a). Its orientation on very weak sustainability causes this scenario to be able to increase the volume of solid waste rapidly (Fig.7c), significantly reduced biodiversity (Fig.7a), and drastically reduce swamp water reserves (Fig.7b). The mass tourism scenario also significantly reduces local community income (Fig. 6a), also drastically decreased environmental investment (Fig. 6b). The illustration above shows that the simulation of the model has followed the logical thinking pattern of mass tourism and relevant to the basics of systems archetype (Kim and Anderson, 1998). The simulation also shows that for 10 years, the number of tourists in the deep ecotourism scenario only increased slightly (Fig.5a). Its orientation to very strong sustainability causes this scenario to reduce the volume of solid waste rapidly (Fig.7c), maintain biodiversity (Fig.7a) and swamp water reserves (Fig.7b). The deep ecotourism scenario can also increase local community income (Fig. 6a) and environmental investment (Fig. 6b). The simulation in this scenario is considered in line with the sustainable management policy of the Rawa Danau as an ecotourism destination in Indonesia.

Conclusions

Considering the various negative impacts of mass tourism, the development of environmentally friendly tourism is now an alternative. That is why people give great expectations to ecotourism, a concept of tourism that integrates economic, social, and ecological conservation interests. As a tropical lowland swamp forest that still remains in Java, the existence of Rawa Danau as an ecotourism destination is important to be explored, because its utilization has not followed the principles of sustainable management. Various problems arise as an impact of mismanagement, e.g.: decrease in forest area due to land conversion, decreased water storage capacity, low local people's income, and empowerment of local communities who do not reach the target. For this reason, a dynamic modeling is then made that integrates various factors in the biophysical, social, and economic dimensions to obtain the best alternative management of ecotourism destinations in the future. Management alternatives are designed in three scenarios: deep ecotourism oriented to very strong/strong sustainability, shallow ecotourism oriented to weak sustainability, and mass tourism oriented to very weak sustainability. System dynamics is used as a method in this study because of its ability to: 1) explore the long-term ecotourism development policies, 2) provide answers to the 'what-if' questions through feedback loops that are built between variables in the system. The results show that deep ecotourism is the most suitable scenario to be implemented in the sustainable management of Rawa Danau as an ecotourism destination in Indonesia. Through this scenario, the control of several parameters that were successfully carried out during the 10 years of simulation are as follows: 1) restrain the growth rate of tourist numbers, the number increased by only 38.4% (from 12,584 people in 2020 to 17,411 people in 2030). This condition is considered as a fairly logical growth because it is not too high so it does not burden the environment, 2) reforesting almost all converted forest land (97.2%) (from 8.57 hectares in 2020 remaining 0.24 hectare in 2030). This condition shows that through this scenario the restoration of forest function is going well, 3) local community income increased by 28.6% (from Rp. 3,500,000 in 2020 to Rp. 4,500,522 in 2030). This condition shows that through this scenario the local community gets adequate economic benefits from ecotourism activities, 4) environmental investment increased by 2,745% (from 0.2% in 2020 to 5.69% in 2030). This condition shows that stakeholders are able to obtain benefits economically, ecologically, and socially

in an integrated manner, 5) biodiversity reduction is relatively small (0.33%) (from 95.0% in 2020 to 94.69% in 2030). This condition shows that through this scenario biodiversity can be maintained well, 6) the decrease in swamp water reserves is relatively small (0.0001%) (from 500 million m^3 in 2020 to 499.9 million m^3 in 2030). This condition shows that through this scenario swamp water reserves can be maintained properly, 7) a significant decrease in the volume of solid waste (99.9%) (from 62,986 kilograms in 2020 to 0.08 kilograms in 2030). This condition shows that this scenario is able to reduce the rate of increase in solid waste volume so that it does not burden the environment.

DETERMINANTS OF HOTEL EMPLOYEES' ELECTRICITY SAVING INTENTION: EXTENDING THE THEORY OF PLANNED BEHAVIOUR[*]

Olawale Fatoki

Department of Business Management, University of Limpopo, Private Bag X1314, Sovenga, 0727, South Africa

Email: olawale.fatoki@ul.ac.za

Abstract. The hospitality industry including hotels makes a significant contribution to job creation and the gross domestic product of many countries. However, the negative environmental effects of hotels include high electricity consumption and emission of green house gases. Employees can help to improve workplace pro-environmental behaviour but the determinants of their electricity saving behaviour has not received thorough empirical investigation. Grounded on on the theory of planned behaviour (TPB), the study examined the determinants of hotel employees' electricity saving intention (ESI). The study extended the TPB by adding two constructs (environmental concern and organisational climate) to the three TPB constructs. Data was collected through the cross-sectional survey method and the Partial Least Square Structural Equation Modelling was used for data analysis. The results showed significant positive relationships between two TPB constructs (attitude and perceived behavioral control) and hotel employees' ESI. In addition, the effects of the two added constructs are significant. Theoretically, the study extended the TPB by adding two constructs and linking them to employees' ESI in the hospitality industry. Recommendations include workplace training on electricity saving.

Keywords: Electricity saving intention; theory of planned behavior; environmental concern; organisational climate; hotels; South Africa

---

1. Introduction

Environmental sustainability has emerged as a vital component of human and business survival. Human needs for natural resources have doubled in the past fifty years with negative environmental impact. Environmental risks continue to be in the forefront of the results of the annual Global Risks Perception Survey (GRPS) and in 2018 accounted for three of the five major risks by likelihood and four by impact (Bahadure, 2017; World Economic Forum, 2018). In South Arica, electricity generation increased by 2.2% between July 2017 and July 2018 and electricity consumption increased by 1.2% within the same period (Statistics South Africa, 2018; International Energy Agency, 2019). Carbon emissions associated with energy production especially from fossil fuels and consumption are a major part of total emissions and an important driver of global climate change (Zierler, 2017; Tvaronavičienė and Ślusarczyk, 2019). The speed of diversity loss has accelerated and the abundance of species has declined by about 60% since 1970 with negative impact on health and social-economic development (Norton *et al*. 2015; Khan and Chang, 2018). In addition, energy prices have increased in South Africa and around the world and global energy supplies have become less stable. In South Africa, it is anticipated that the price of electricity will rise by 9.41% in 2019/20 and this is expected to double the expected inflation rate of 4.5% (Akpan and Akpan, 2012; Tang *et al*. 2019; National Energy Regulator of South Africa, 2019). Also, public concern about environmental issues has increased and this has stimulated eco-friendly products and services. Green consumption is on the increase as many customers are aware of the effect of their buying decisions on the environment (Chen and Tung, 2014; Verma and Chandra, 2017). Due to external pressure from customers and government and the increase in the cost of electricity, many firms have started to introduce energy saving measures. The participation of employees is crucial for the success of a company's energy saving activities. Energy saving behaviour can be described as the reduction of energy use by individuals. Electricity saving intention can be described as the self-commitment of an individual to participate in electricity saving behaviours. Reducing energy use through conservation is one of the more cost effective ways to significantly decrease greenhouse gas emissions. Electricity saving is a pro-environmental behaviour (Pollard, 2015; Sony and Mekoth, 2018; Ru *et al*. 2018).

Hotels are energy intensive facilities, with high energy costs. The consumption of energy by hotels is higher than other commercial buildings. Energy costs account for 3-6% of overall operating costs of hotels. Hotels are associated with high energy wastage and low energy efficiency with 42% of the energy used to heat and cool spaces in hotels wasted. However, rising energy costs, attention of guests to sustainability and the rise of green movement in the hotel industry have increased the focus of hotels on energy management initiatives (Mensah and Blankson, 2013; Prud'homme, and Raymond, 2016; Cingoski and Petrevska, 2018).

The theory of planned behaviour (TPB) is the most frequently used theory to predict pro-environmental intentions and behaviours (Pollard, 2015; Ru *et al*. 2018). The TPB by Ajzen (1991) posits that intention positively affects actual behaviour and behavioral intention is influenced by three factors namely attitude, subjective norms and perceived behavioural control. Chen and Tung (2014) argue that despite the broad effectiveness of the TPB in explaining pro-environmental behaviour, many studies have enriched the explanatory effect of the theory by adding other constructs. This study extends the TPB by adding two new constructs (environmental concern and organisational climate) to develop a model of electricity saving purchase intention for hotel employees. Researchers on sustainability issues and pro-environmental behaviour should develop a multidisciplinary viewpoint that includes both micro and macro factors (Joshi and Rahman 2015; Sobiegalla *et al*. 2018; Sarma *et al*. 2019).

The study aims to examine the effect of these five variables on hotel employees' electricity saving intention (ESI). The study will contribute to knowledge in the following ways. First, the electricity saving behaviour of individuals has become an emerging area of research. However, extant research at the individual level has focused

on households rather than the workplace (Gao *et al*. 2017; Chang *et al*. 2018). Furthermore, while individuals need to pay for electricity consumption in households, electricity consumption in the workplace is almost free of charge to the employee. This makes electricity more easily wasted in workplaces compared to households (Gao *et al*.2017; Wesselink *et al*. 2017). Second, there is a research gap with respect to employees' electricity saving intention and behaviour in organisations and studies that have used the extended TPB to examine hotel employees' electricity saving intention in South Africa are scarce.

2. Literature review

2.1 Electricity saving behaviours
Electricity saving behaviour can be described as the behaviours performed by individuals to reduce overall electricity use and can be broadly divided into two categories. (1) Habitual energy-saving behaviours: These focus on continuous efforts to reduce electricity use by curtailment measures. Examples of habitual electricity saving behaviours include reducing or avoiding the usage of air-conditioners and turning the power off when appliances are not used (2) one-shot purchasing behaviours: This involves the replacement of old technology with high electricity use with new technology with low energy use and the purchase of more-efficient technology.

2.2 Theory of planned behaviour and electricity saving intention (ESI)
ESI can be described as the self-commitment of an individual to participate in electricity saving behaviours. The TPB is the most commonly used theory to predict pro-environmental behaviour (Pollard, 2015; Ru *et al.*, 2018). The TPB by Ajzen (1991) contends that intention predicts actual behaviour and intention is influenced by attitude, subjective norms and perceived behavioural control. In addition, other variables can be included in the TPB as long that they can be shown to improve the explanatory power of the model and are reasonable to explain a range of behaviour (Ajzen, 1991; Tommasetti *et al*.2018). Two additional constructs (environmental concern and organisational climate) are added as predictors of employees' ESI.

2.2.1 Attitude and electricity saving intention
Attitude towards the behaviour determines the extent to which a person has a favourable or an unfavourable assessment of a certain behaviour. A more favorable attitude towards a certain behavior by an individual should lead to a stronger intention to perform the behavior (Lin *et al*. 2015). Empirical literature is not conclusive about the effect of attitude on pro-environmental behaviour of individuals. Ha and Janda (2014) show that the attitude towards a green product has a strong effect on intention. Greaves *et al.* (2013) find that attitude has a significant positive relationship with the intention to engage in pro-environmental behaviour. The findings of the study by Wells *et al*. (2016) reveal that attitude has a positive effect on environmental behaviour both at home and in the workplace. Wang *et al*. (2014) show that environmental attitudes significantly influence energy-saving behavior. However, studies such as Kaiser *et al*. (1999), Park and Yang (2012) report a weak relationship between environmental attitude and environmental behaviour. If an individual considers electricity saving behaviour in the workplace as beneficial, he/she will hold a positive attitude and this can influence the intention to save electricity (Gao et *al*. 2017; Ru *et al*. 2018). Therefore, a more favorable environmental attitude by an individual should lead to a stronger intention to engage in electricity saving behaviour. Consequently, it is hypothesised that (H1): attitude towards energy saving positively affects employees' ESI.

2.2.2 Subjective norms (SNs) and energy saving intention
SNs indicate the possibility that individuals or groups that are important to an individual will like or dislike the performance of a particular behaviour (Ajzen, 1991). Greaves et al. (2013) find that SNs positively affect employees' intention to switch off computers when leaving their desk for more than one hour and recycle waste at work. The results of the study by Wang *et al*. (2014) show that SNs significantly affect the energy saving intention of city residents. Zierler (2017) argues that the relationship between SNs and intentions and behaviours

is a subject of much debate with varying empirical findings and Armitage and Conner (2001) remark that SNs tend to vary considerably across behaviours. Abrahamse and Steg (2011) find that SNs do not contribute to the explanation of intentions when attitudes and perceived behavioural control are controlled for. However, the opinions of a person or group of importance to an individual may influence the intention of that individual to engage in electricity saving as an employee in the workplace. It is hypothesised that (H2): SNs positively affect employees' ESI.

2.2.3 Perceived behavioural control (PBC) and electricity saving intention
PBC can be described as the perceived difficulty or ease of conducting a behaviour (Ajzen, 1991). There is a significant positive relationship between PBC and intention to use energy savings devices (Pollard (2015; Lin *et al*. 2015). However, Park and Yang (2012) and Kranz and Picot (2012) did not find a significant association between PBC and consumers' intention to adopt smart metering technology. The availability of resources and skill about electricity saving should positively influence behavioural intention. It is hypothesised that (H3): PBC positively affects employees' ESI.

2.2.4 Organizational electricity saving climate (OESC) and electricity saving intention
Organisational climate is a construct that has major implications for understanding human behaviour in organisations. Organisational climate can be described as the shared perception of employees about their work environment, particularly how policies and procedures are translated into tacit guidelines and practices. Pro-environmental organisational climate depicts the perception of employees about their organisations' pro-environmental policies, procedures, and practices (Castro and Martin, 2010; Norton *et al*. 2012). Zientara and Zamojska (2015) find that green organisational climate has a direct impact on organisational citizenship behaviour for the environment in hotels. However, Zhang, Wang and Zhou, (2014) find that OESC does not significantly affect electricity saving intention. This study argues that the positive perception of employees about the pro-environmental organisational climate of their organisation can positively impact on electricity saving intention. It is hypothesised that (H4): OESC positively affects employees' ESI.

2.2.5 Environmental concern (EC) and electricity saving intention
Dunlap and Jones (2002, p 484) define EC as "the degree to which people are aware of environmental problems and support efforts to solve them and/or indicate a willingness to contribute personally to their solution". Li *et al*. (2019) find that EC is significantly positively correlated with the willingness to purchase energy-efficient appliances. EC positively affects people's intention to use a park-and-ride facility (De Groot and Steg, 2007) and consumers' intention to adopt hybrid electric vehicles (Wang *et al*. 2016). EC has a significant positive effect on environmental knowledge, behavioral intention and environmentally friendly behaviour ((Pagiaslis and Krontalis, 2014; Newton *et al*. 2015). It is hypothesised that (H5): EC positively affects employees' ESI.

3. Research methodology

The study followed the quantitative research method and the data was collected through the cross-sectional survey method from participants in the Gauteng Province of South Africa. Participating hotels were conveniently selected from the website of the Tourism Grading Council of South Africa and were contacted by the researcher through a formal letter that explained the purpose of the study. Self-administered questionnaires were completed by employees of the participating hotels (see Appendix). Each participant was given a month to complete the questionnaire and was reminded weekly through emails and phone calls obtained during questionnaire distribution. The researcher pre-tested the questionnaire and the results led to the removal of sensitive information such as the name of the participant or hotel to ensure anonymity. Descriptive analysis and the Partial Least Square Structural Equation Modelling were used to analyse data.

4. Results

4.1 biographical characteristics

Thirty-three out of the forty-two hotels contacted particiopated in the survey. 660 (20 per hotel) questionnaires were distributed to the participants and 342 questionnaires were returned.

Table 1. Biographical information of the respondents.

Biographical Characteristics	Frequency ($N = 342$)
Educational qualification	
Matric	161
Post–Matric qualifications	181
Gender	
Female	163
Male	179
Age (years)	
20 years and less	0
21–30	128
31–40	157
41–50	52
Above 50	5
Work experience	
1–5	160
Above five years	182

Table 1 depicts the biographical characteristics of the survey participants. The results indicated that the majority of the respondents are males, in the 31-40 age bracket and with more than five years work experience.

4.2 Descriptive statistics

Table 2. Descriptive statistics

Construct	Mean	Standard deviation (SD)
Attitude	3.85	1.07
SNs	3.15	1.01
PBC	4.02	1.02
EC	4.05	0.99
OESC	3.90	1.01
ESI	4.40	1.06

The results of the descriptive analysis are presented in table 2. Attitude has a mean score of 3.85 with SD of 1.07. The mean score of SNs is 3.15 with a SD of 1.01. The mean score for PBC is 4.02 with a SD of 1.02. The mean score of ECis 4.05 with a SD of 0.99 and the mean score of OESC is 3.90 with a SD of 1.01. The mean score of ESI is 4.40 with a SD of 1.05.

3.3 Structural equation modelling

3.3.1 Measurement model

Table 3. Convergent validity

Construct	Measurement items	Loading	Cronbach's alpha	Composite reliability	AVE
Attitude (A)	A1	0.84	0.79	0.89	0.70
	A2	0.84			
	A3	0.79			
	A4	0.83			
Subjective norms (SNs)	SNs1	0.88	0.72	0.83	0.66
	SNs2	0.81			
	SNs 3 deleted	0.41			
Perceived behavioral control (PBC)	PBC1	0.84	0.84	0.86	0.69
	PBC2	0.76			
	PBC2	0.80			
Environmental concern (EC)	EC1	0.84	0.77	0.88	0.64
	EC2 deleted	0.49			
	EC3	0.78			
	EC4	0.76			
	EC5	0.83			
	EC6	0.80			
	EC7	0.84			
	EC8	0.86			
Organisational Energy Saving climate (OESC)	OESC1	0.78	0.75	0.91	0.67
	OESC2	0.81			
	OESC3				
Energy saving intention (ESI)	ESI1	0.82	0.81	0.87	0.64
	ESI2	0.78			
	ESI3	0.80			

Table 4. Discriminant validity

Construct	ESI	A	SN	PBC	EC	OESC
ESI	**0.80**					
A	0.79	**0.84**				
SN	0.73	0.77	**0.85**			
PBC	0.64	0.61	0.72	**0.82**		
EC	0.79	0.68	0.72	0.75	**0.82**	
OESC	0.68	0.62	0.71	0.69	0.71	**0.79**

Diagonals in bold represent the square roots of AVEs

Table 3 and table 4 depict the discriminant and the convergent validity. Four constructs (attitude, perceived behavioural control, organisational climate and energy saving intention) have all items greater than 0.708. However subjective norm and environmental concern have one item each with loading below 0.708. The two items were deleted. The results also indicate that the composite reliability is between 0.70 and 0.95, Cronbach's

alpha values for the constructs are above 0.70 and the the square roots of AVEs are higher than the correlations among the latent variables ((Hair *et al*. 2019).

3.3.2 Structural model assessment

Following the suggestions by Hair et al. (2019), the likelihood of common method bias (CMB) was examined. The VIFs for the constructs of the study were lower than 3.3 suggesting that the model is not constrained by CMB (Henseler *et al.,* 2015). The R^2 obtained by the study is 0.521 indicates a high level of predictive accuracy of the model. The original TPB model accounted for 44.9% of the variance. This indicates that inclusion of environmental concern and organisational energy saving climate increased the explained variance by 7.2%. The value of the goodness of fit (GIF) is 0.59 suggesting a good model fit and the (Q^2) using the cross validated communality is 0.56 which supports a predictive model. The effect size, f^2, ranged from 0.01 to 0.12 indicating small to medium effect sizes and the standardised root mean square residual of 0.03 is indicative of a good model fit. The results of the path coefficients and T-statistics using the bootstrapping technique are depicted in table 5.

Table 5. Path coefficient and T-statistics

Hypothesised path	Standardised Beta	T-statistics	Decision
H1 A to ESI	0.307	6.244*	Accepted
H2 SNs to ESI	0.108	0.559	Rejected
H3 PBC to ESI	0.263	6.852*	Accepted
H4 EC to ECI	0.225	3.775*	Accepted
H5 OESC to ECI	0.173	3.284**	Accepted

*P<0.01; ** <0.05

The results H1 (β =0.307, T= 6.244, p<.001). H3 (β= 0.263, T= 7.216, p<.001) and H3 (β =0.263, T= 6.852, p<.001) support significant positive relationships between attitude and perceived behavioural control and electricity saving intention. Thus H1 and H3 are not rejected. The results for H2 (β =0.108, T= 0.559, p>.05) is not significant. Thus H2 is rejected. Environmental concern (β=0.225, T=3.775, p<0.01) and organisational energy saving climate climate (β =0.173, T =3.284, p<0.05) have significant positive relationships with electricity saving intention. Thus H4 and H5 are not rejected.

4   Discussion

Electricity saving behaviour can be described as the reduction of electricity use by individuals and electricity saving intention is the plan of an individual to participate in electricity saving behaviours. The TPB is the most commonly used theory to predict pro-environmental behavioural intentions including electricity saving intention. This study extends the TPB by adding two new constructs (environmental concern and organisational climate) to the three constructs of the TPB. The findings indicated that there is a significant positive relationship between attitude and PBC and ESI. H1 and H3 of the study are supported. The study did not find a significant relationship between SNs and ESI and H2 is not supported. The results also indicated significant positive relationships between two additional constructs (EC and OESC) and ESI. Therefore, H4 and H5 of the study are supported. The findings of this is supported by both theoretical and empirical literature. The TPB shows that attitude and perceived behavioral control can predict behavioral intention. This is supported by the findings of this study. However, the effect of SNs is not significant. Pollard (2015) finds that attitude toward sustainability at work has a strong association with the use of energy savings devices. The study by Wells *et al*. (2016) revealed that attitude has a significant positive positive effect on environmental behaviour both at home and in the workplace. There is a significant positive relationship between PBC and to intention to use energy savings devices (Pollard (2015; Lin

et al. 2015). Gao *et al*. (2017) find that SNs have an insignificant effect on intention to save energy in workplaces. Organisational climate has a positive effect on hotel employees green behaviour in the workplace (Chou, 2014). Li *et al*. (2019) find that environmental concern is positively correlated with the willingness to purchase energy-efficient appliances.

5. Conclusion

This study extended the TPB by adding two new constructs (environmental concern and organisational climate) to the three constructs of the TPB. The study investigated the effect of three TPB constructs and two additional constructs on hotel employees' ESI. The findings indicate that there is a significant positive relationship between attitude and PBC and employees' ESI. The study did not find a significant relationship between SNs and ESI. The findings also indicate significant positive relationships between two additional constructs (environmental concern and organisational electricity saving climate) and ESI.

The findings of the study have some policy implications. Employees must develop a more favorable environmental attitude. Therefore, factors such as turning off lights and air conditioners when leaving the office can help to save electricity. In addition, attending workplace training on electricity saving mechanisms will be a proactive way to reduce electricity consumption. Hotels must also make available resources, knowledge and skills about electricity saving. This can be achieved by the replacement of old technology with high electricity use with new technology with low energy use. The reward of employees must take pro-environmental behaviour into consideration. To improve, organisational electricity saving climate, hotels must develop and communicate their sustainability policy to employees. The limitations of the study include the use of convinience sampling which may lead to sampling bias and the focus on 342 hotel employees in one province limits the generalisability of the findings. Other studies can examine the effect of environmental passion and workplace spirituality on employees' ESI.

Appendix: Questionnaire

Concept	Survey items	Response category	Adapted from
Attitude	1. I think that saving electricity in my workplace is useful to protect the environment. 2. I think that saving electricity in my workplace is significant to reduce carbon emissions. 3. I think that saving electricity in my workplace is valuable to reduce electricity shortage. 4. I think that saving electricity in my workplace is a wise decision.	I strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly agree	Ajzen (1991) and Gao *et al.* (2017
Subjective norms	1. My colleagues that that I should save electricity in the workplace. 2. My managers think that I should save electricity in the workplace. 3. Other people that are important to me think that I should save electricity in the workplace.	I strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly agree	Ajzen (1991) and Gao *et al.* (2017
Perceived behavioral control	1. I think that I am capable of saving electricity in my workplace. 2. I have the knowledge and skill to save electricity in the workplace.	I strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly agree	Ajzen (1991) and Gao *et al.* (2017

	3. Whether or not I save electricity is completely up to me.		
Environmental concern	1. I am extremely worried about the state of the world's environment and what it means for the future 2. Mankind is severely abusing the environment 3. When mankind interferes with nature, it often produces disastrous consequences 4. The balance of nature is delicate and easily upset 5. Human must live in harmony with nature in order to survive 6. I think that environmental problems are important 7. I think that environmental problems cannot be 8. I think that we should care about environmental problems.	I strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly agree	Chen and Tung, 2014 and Yadav and Pathak (2015)
Organisational electricity saving climate	1. Electricity saving is encouraged in my workplace 2. My workplace puts value on electricity saving 3. My workplace is actively committed to electricity saving.	I strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly agree	Zhang *et al.* (2014)
Electricity saving intention	1. I am willing to save electricity in my workplace. 2. I intend to engage in electricity saving activities in my workplace 3. I plan to save electricity in my workplace	I strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly agree	Ajzen (1991), Chen and Tung (2014) and Zhang *et al.* (2014)

Abstract. The article examines the market for promising memristor-based memories for smart systems. The implementation of smart systems is characterized by the widespread use cyber-physical systems, predictive maintenance, AR/VR (Augmented/Virtual Reality) technologies, the Internet of Things (IoT), and Machine Learning algorithms. To stimulate their development, an increasing amount of computational resources and new data storage technologies is required. The current study aims to analyze the development of today's memristive technologies market in the context of their influence on the development of smart systems. The authors discuss the key stages of the market's formation and assess the possible effect of memristive technology on various spheres of society's life. The research results show that the application of memristive technology can affect the development dynamics of both data mining and promising data storage systems. The estimates obtained demonstrate that the memristor market is highly competitive and there are a considerable number of active participants operating on it. The majority of companies expand their market presence by entering various end-user segments. The annual market growth rate will average about 80% and reach an estimate of USD 8.9 billion by 2024 and USD 13.5 billion by 2027.

1. Introduction

The rapid development of digital technology and the widespread adoption of smart systems have emphasized the key role of Big Data management. There are a number of major trends in the digital transformation of industry that are worth mentioning: autonomous robots (Yudin et al., 2017); cloud computing and storage (Che, Safran & Peng, 2013); CAD systems (modeling and simulation) (Demin &Vlasov, 2017); the Internet of Things (Berdyugina, Krivoshein & Vlasov, 2018); and augmented reality (Che, Safran & Peng, 2013). These technologies, when introduced in manufacturing, will lead to the creation of smart factories and initiate a new era in all sectors of industry, which can result in the fourth industrial revolution (The fourth…, 2017), or Industry 4.0 (Witten & Frank, 2016). For this to happen, vast computational resources and storage space are needed.

Computational resources and data storage technology are approaching their maximum capability year after year. Non-volatile CMOS-based memory has already reached its full potential. However, data volumes keep growing, so there is a need to discover a brand-new principle of data storage (Vasilyev & Chernov, 2012). Solutions in this field are characterized by the application of cyber-physical systems (Lee, 2006; Lee & Seshia, 2011), predictive maintenance (Grigoriev et al., 2018), AR/VR (Augmented/Virtual Reality) technologies (Che, Safran & Peng, 2013), the Internet of Things (IoT) (Lee, 2006; Lee & Seshia, 2011), Machine Learning algorithms (Whitaker et al., 2018), and decentralized architecture (Blockchain technology) of Big Data analysis and processing (Che, Safran & Peng, 2013; Muraviev et al., 2019). However, among other solutions, this is a memristor that is considered a promising device in numerous analog and digital applications, especially in memory chips, logic circuits, and neural networks.

The *purpose* of the paper is to analyze the development of the market for the modern component base of smart systems based on memristor technology that ensure the implementation of intelligent data processing algorithms and methods for their storage.

2. Literature review

Digital transformation involves manipulating not only technical, but also economic, social and other data that are necessary to manage digital production processes in a more effective manner (Litau, 2018a,b). A continuous increase in information volumes has led to the creation of a separate class of data, namely Big Data (Che, Safran & Peng, 2013; Muraviev et al., 2019). To process large volumes, network computing technology has to be used (Veretennikov, 2017), whereas the creation of the memristor component base is believed to be a promising solution in the field of data storage.

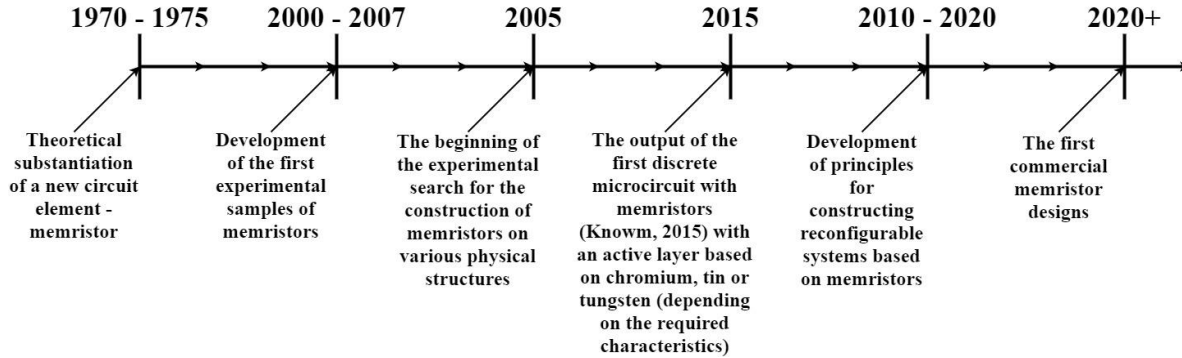
A memristor is a non-linear two-terminal electrical component relating electric charge and magnetic flux linkage (Jeong & Shi, 2019). There are various methods for fabricating memristors. The most popular of them are lithography (Jung, 2004), atomic layer deposition (Emelyanov et al., 2015), pulsed laser deposition (Puurunen, 2005) and sputter deposition (Wasa & Hayakawa, 1993). The technological evolution of the memristor-related component base is presented in Fig. 1. The research studies devoted to memristors are gaining in popularity. The number of international scholarly publications increased from 2 pieces in 2005 to 48 pieces in 2015. The number of international patent applications is also rising – from 40 in 2005 to 158 in 2015 (Borodina et al., 2017).


Fig. 1. Memristor Development Time line

When analyzing the development trends in memristor technologies, it is worth noting their high versatility (Ho, Huang & Li, 2009). In terms of memory chips, memristors can be applied in cell structures of resistive random-access memory (RRAM) and in memristor-based content addressable memories (MCAM) using a combination of memristor and memory cell technology, as well as in multilevel memristor memory (MLMM) (Yener & Kuntman, 2012). Due to the powerful capabilities of memristor technology, Ho and Huang (2009) suggested using these advantages for making calculations directly inside the system, eliminating the need to upload data to the cloud and thus increasing the security of such systems. Memristor-based logic has a remarkable ability that allows arranging memory cells on a single chip. Memristors can be applied in the development of switching units in field-programmable gate array (FPGA) (Sampath, Mane & Ramesha, 2015).

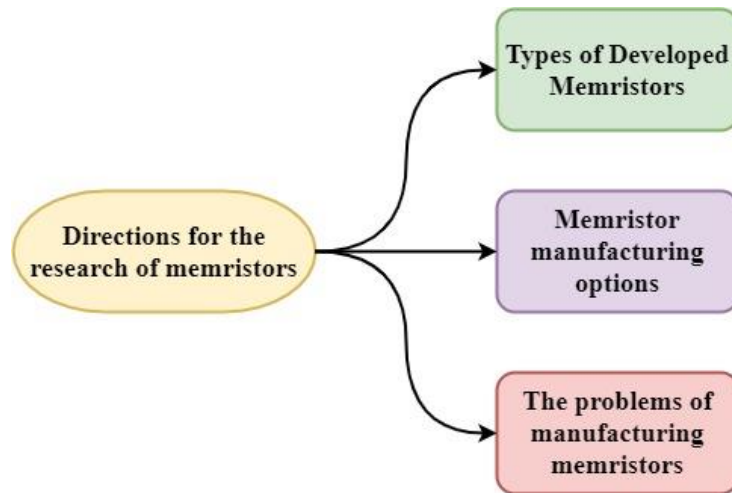
There are three main directions for the research of memristors: developing various types of memristors, searching for memristor manufacturing options, and dealing with the problem of manufacturing memristors (Sherief et al., 2019) (Fig. 2).


Fig. 2. Directions for the research of memristors

Currently, the memristor market's investment attractiveness is at its early stage of development as there is lack of devices ready for mass production (TMR, 2017). The formation of the memristive technology market is affected by a basic operational contradiction (Fig. 3): if a material of better quality and of higher price is used to fabricate memristors, the quality of the memory created is enhanced in terms of the number of writes and response time;

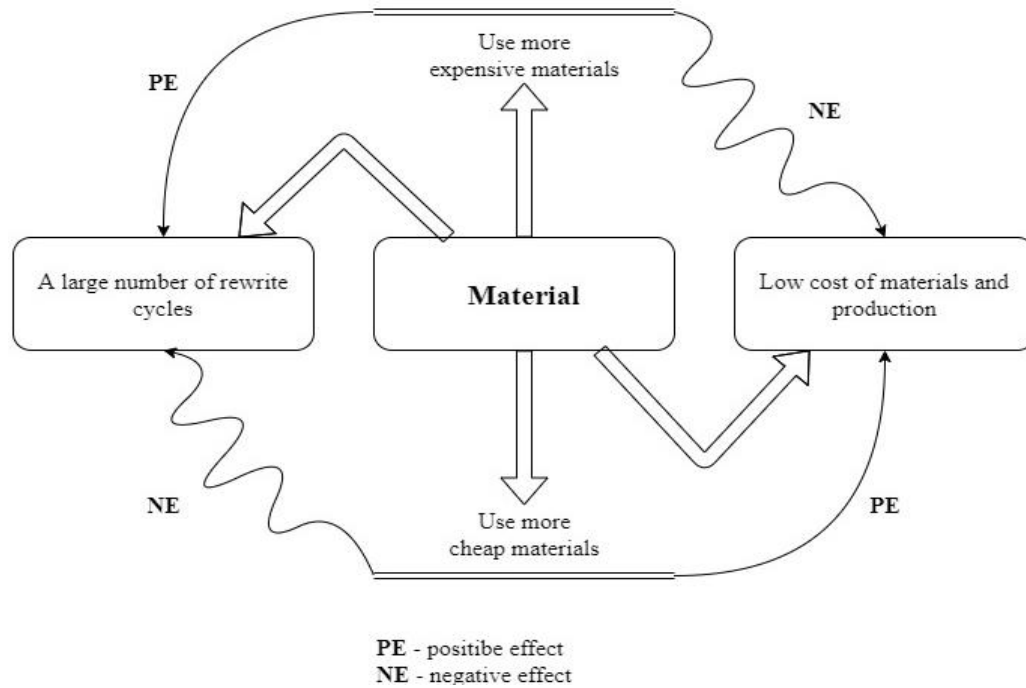
however, it causes a serious rise in production costs and makes it difficult to start mass production. The choice of a memristor material determines the "memory strength" reflected in the number of rewrite cycles and the total cost of production.


Fig. 3. Operational controversy scheme

Memory devices are increasingly becoming a bottleneck in data storage and data retrieval processes, and this limits storage performance. To improve computing speed significantly, scientists are striving to design smaller and denser memory devices that operate at high speed and consume low power (RM, 2018). With the advent of advanced technologies, data storage systems process more information than ever before. To do so, they should be of high performance, accessible, scalable, and manageable (Shukla & Sharma, 2017). The main studied parameters of memristor technologies and their influence are shown in Table 1.

Table 1. Effect of memristive technologies parameters on their properties

Parameter	Effect
Storage density	Capacity increase (Vasilyev & Chernov, 2012)
Response time	Increased data processing speed (Matkarimov, 2018)
Synaptic properties	Empowering Artificial Intelligence (Snider et al., 2011)
Power efficiency	Computing systems autonomy (Ho, Huang & Li, 2009), power capacity (MM, 2017)

The forecast properties of memristors and the current memories are compared in Table 2 (Sherief et al., 2019; TMR, 2017; RM, 2018; Shukla & Sharma, 2017).

Table 2. Memory-related memristor properties

Property	Memristor	PCM	STTRAM	DRAM	Flash	HDD
Storage density (F^2)	<4	8–16	37–64	6–8	4–6	2/3
Energy per bit (pJ)	0.1–3.0	2–27	0.1	2	10000	$1–10 \times 10^9$
Read timing (ns)	10–100	20–70	10–30	10–50	25000	$5–8 \times 10^6$
Write timing (ns)	~10	50–500	13–95	10–50	200000	$5–8 \times 10^6$
Retention	Years	Years	Weeks	<<Seconds	Years	Years
Rewrite cycle	$>10^{12}$	10^7	10^{15}	10^{15}	10^6	10^4

Based on recent studies, it can be concluded that the use of memristor technology will affect the dynamics of the development of both data mining and promising data storage systems (Vasilyev & Chernov, 2012; Vera-Tasama, Gomez-Cano & Marin-Hurtado, 2019; Marani, Gelao & Perri, 2015).

3. Methods

Designing an approach to the problem of analyzing the dynamics of the memristor market development includes the formulation of the theoretical framework of the research, analytical models, search queries, hypotheses, as well as the identification of the factors that can affect the nature of the study.

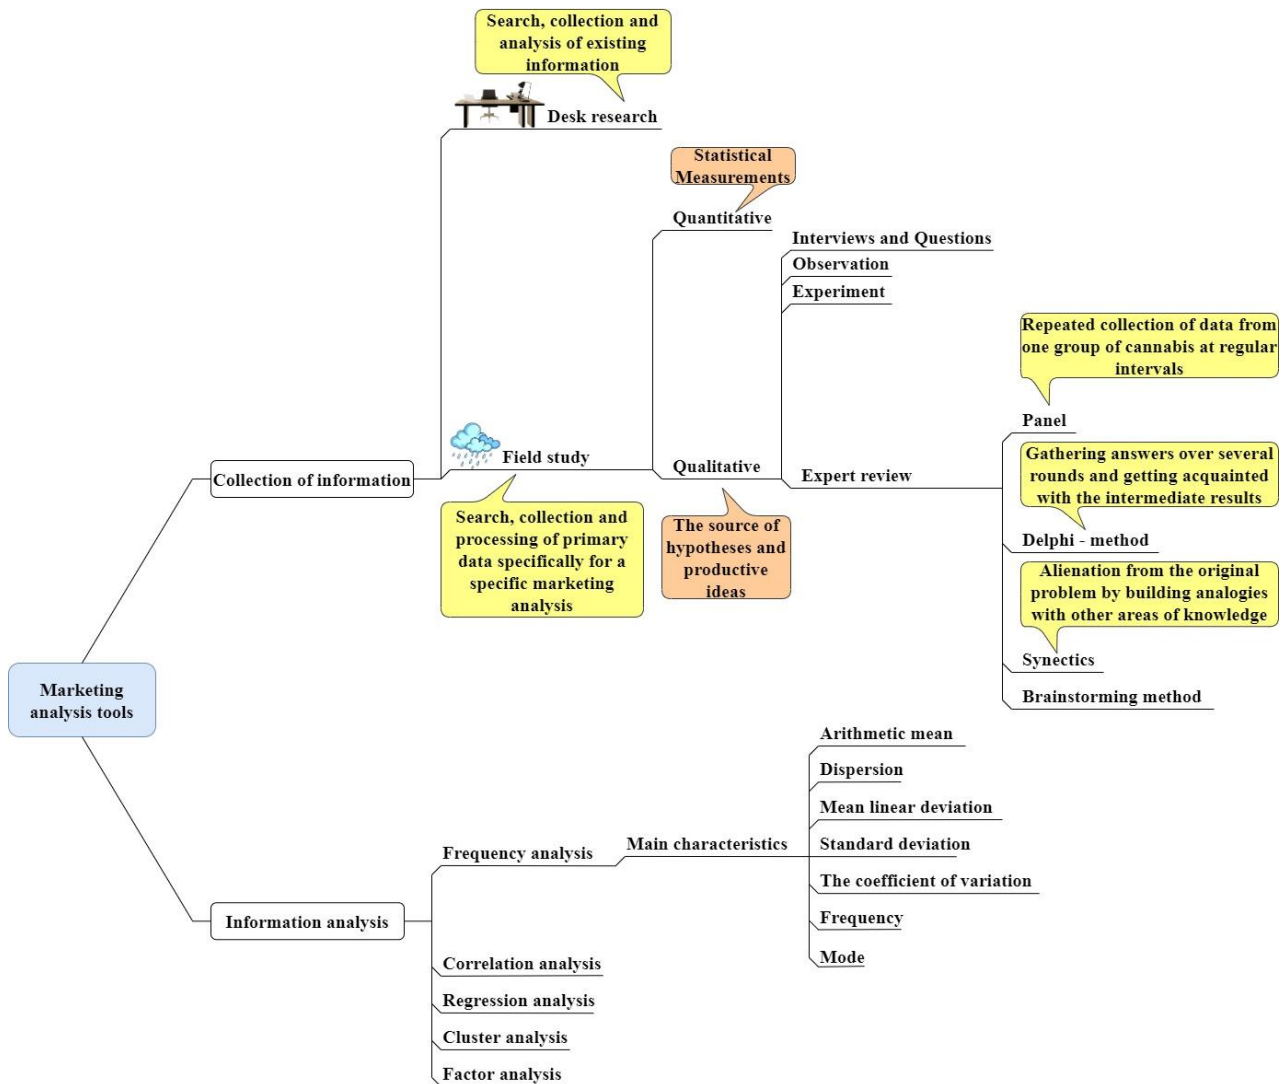
Analytical research methods are diverse (Fig. 4).


Fig. 4. System analysis methods

The expert approach, upon which the current study is built, should be discussed in more detail. Methods of expert assessments are methods of organizing work with experts and processing opinions of experts expressed in a quantitative and (or) qualitative form.

The research procedure suggests direct communication of expert opinions.

When analyzing expert assessments, a variety of statistical methods can be utilized (Table 3): consistency check (or expert classification, if no consistency is observed) and averaging expert opinions within an agreed group. It is a widespread approach to use simultaneously the mean ranks method and the median ranks method.

Table 3. Methods and algorithms for analyzing expert assessments

Method	Algorithm
Mean ranks method	Calculation of the sum of ranks assigned by experts → Dividing the amount by the number of experts → Final ranking for calculated average ranks
Median ranks method	Sort expert scores for each item in non-decreasing order → Choose a median (centrally ranked) → Final median ranking
Clustered ranking matching method	Selection of conflicting pairs of objects → Formation of clusters of the final clustered ranking → Cluster ordering

Applying the methods from Table 3, we have assessed the dynamics of the memristor market development by analyzing expert panels, as well as summarizing the data from statistical reports (MMR, 2019; MW, 2020; Kastalskiy, 2017; Berd, 2014; Pechatnick, 2010). Quantitatively the market is assessed according to basic indicators. The level of concentration of the industrial market is one of the key characteristics of its structure. Other characteristics of the market are taken into account along with concentration. The structure of the industry market is revealed by three basic indicators – the number of suppliers, the suppliers' market share, and the market concentration indicators (Kuzmin, Volkova & Fomina, 2019).

The qualitative assessment of the representativeness of the sample for identifying the dynamics of the memristor market development indicators was based on the results of several studies that concentrated on exploring the

trends in the memristor market (TMR, 2017; RM, 2018; Shukla & Sharma, 2017; MM, 2017; MI, 2020; FMI, 2016; IA, 2020; MRO, 2015; AMR, 2016; TIP, 2020). When performing the analysis, we used the data from patent systems Federal Institute of Industrial Property (www.fips.ru), United States Patent and Trademark office (www.uspto.gov), European Patent Office (www.espacenet.com), application database of the World Intellectual Property Organization (www.wipo.org), as well as scientific publication and citation databases (Web of Science, Scopus, eLIBRARY.RU).

4. Results

Key factors that navigate the growth in the global memristor market size are advantages of memristors over other memories, increase in number of industrial robots, which require larger memory, increase in demand of tablets, watches, smart phones and other smart wearable devices, whose power capacity can significantly enhance due to memristors (MMR, 2019). According to Cisco Systems' estimates, by 2022 the number of wearable devices in the world can reach 1,105 billion units as compared to 593 million units in 2018 (Fig. 5).
Fig. 5. The use of wearable devices with a forecast up to 2022 by region
Source: (Statista, 2020).

The growing popularity of the IoT and increasing demand for neural networks open up new opportunities for participants in the memristor technology market. In 2018, the memristors market was valued at USD 278.05 million (PRN, 2019). Estimates of the market are increasing every year. Numerous forecasts indicate that the annual market growth rate will average about 80% and reach an estimate of USD 8.9 billion by 2024 and USD 13.5 billion by 2027, and there is still more to come (MI, 2020; FMI, 2016; IA, 2020).

The interest of researchers in memristors is constantly growing. Figure 6 shows the increase in the number of publications on memristors: by 2020, their number has increased 8 times. Figure 7 illustrates an increase in the

number of memristor-related articles (according to the publication archive of Web of Science, Scopus and eLIBRARY.RU). The rise is even more significant here.
Fig. 6. The number of publications on memristor technology
Source: (Sherief et al., 2019; TMR, 2017; RM, 2018; Shukla & Sharma, 2017).
Fig. 7. Cumulative publication per year
Source: (Sherief et al., 2019; TMR, 2017; RM, 2018; Shukla & Sharma, 2017).

The memristor market is highly competitive. Figure 8 shows that the key players and investors of the market are the following: HP development company, L.P. (www.8.hp.com); Intel Corporation (www.intel.ru); Knowm Inc (knowm.org); Micron Technology, Inc. (www.micron.com); Panasonic Corporation (www.panasonic.com); Rambus Incorporated (www.rambus.com); Samsung (www.samsung.com); San Disk Corporation (www.shop.westerndigital.com/sandisk); Sk Hynix Inc. (www.skhynix.com); and Toshiba Corporation (www.toshiba.co.jp . Most companies expand their market presence by entering various end-user segments. The effectiveness of such a strategy is grounded by forceful arguments (Toomsalu et al., 2019; Chernova et al., 2019).
Fig. 8. Activities of global manufacturers of memristive technologies
Source: (MRO, 2015).

According to Accurize Market Research (AMR, 2016), the global memristor market is geographically categorized into North America – 33%, Europe – 27%, Asia Pacific – 24%, rest of the world – 16%. North America is one of the most significant markets for memristors (Fig. 9). This is due to the high level of investment in research and development from local market players, many of which are located in the United States (Lambert, 2020). The country is also among the key participants in most memristor applications, such as neuromorphic computing, car electronics, flexible electronics, the IoT, and industrial robotics. The region's investments in edge computing and systems on a chip (SoC) are significantly higher compared to investments from companies from other regions of the world.
Fig. 9. The scale of the world market of memristors on a geographical basis
Source: (AMR, 2016).

107

When analyzing global trends in the development of memristive technology, it can be stated that they are passing through the second stage of development (Fig. 10). The first stage of this technology's development is over. Its major result is the discovery of the possibilities of creating memristors. At the moment, global memristor manufacturers are actively exploring the possibility of improving the current results to pass through the second stage and enter the third one.
Fig. 10. The development trend of memristive technology

As with the development of processors, memristive technology will improve its capacity in the process of its further introduction and integration. In this regard, we can assert that memristors will be going through at least 4 development stages starting from single-thread systems to multi-thread ones that will take the form of a memristor processors network (Potkina & Kholopova, 2014). With the emergence of first memristor processors capable of integrating into common computing systems, memristive technology will start being introduced and applied across all countries.

However, despite all the existing inventions, the introduction of this technology can be projected for the next decade only, since there are still a vast number of unresolved technological and economic issues, in particular, the need for substantial investment in re-equipment. Based on the analysis of the current situation using the data from patent reports and publication activity (Kastalskiy, 2017; Berd, 2014; Pechatnick, 2010; Politbook, 2020), it is possible to forecast future change in the memristive technologies market (Fig. 11).
Fig. 11. Projected estimates for the implementation of memristive technologies by 2030, %

It can be assumed that the first breakthrough in memristive technology will happen in the field of data storage. A fundamentally new type of memory and its properties allow storing much larger amounts of data, while production costs are comparable to current high-budget solutions.

5. Discussion

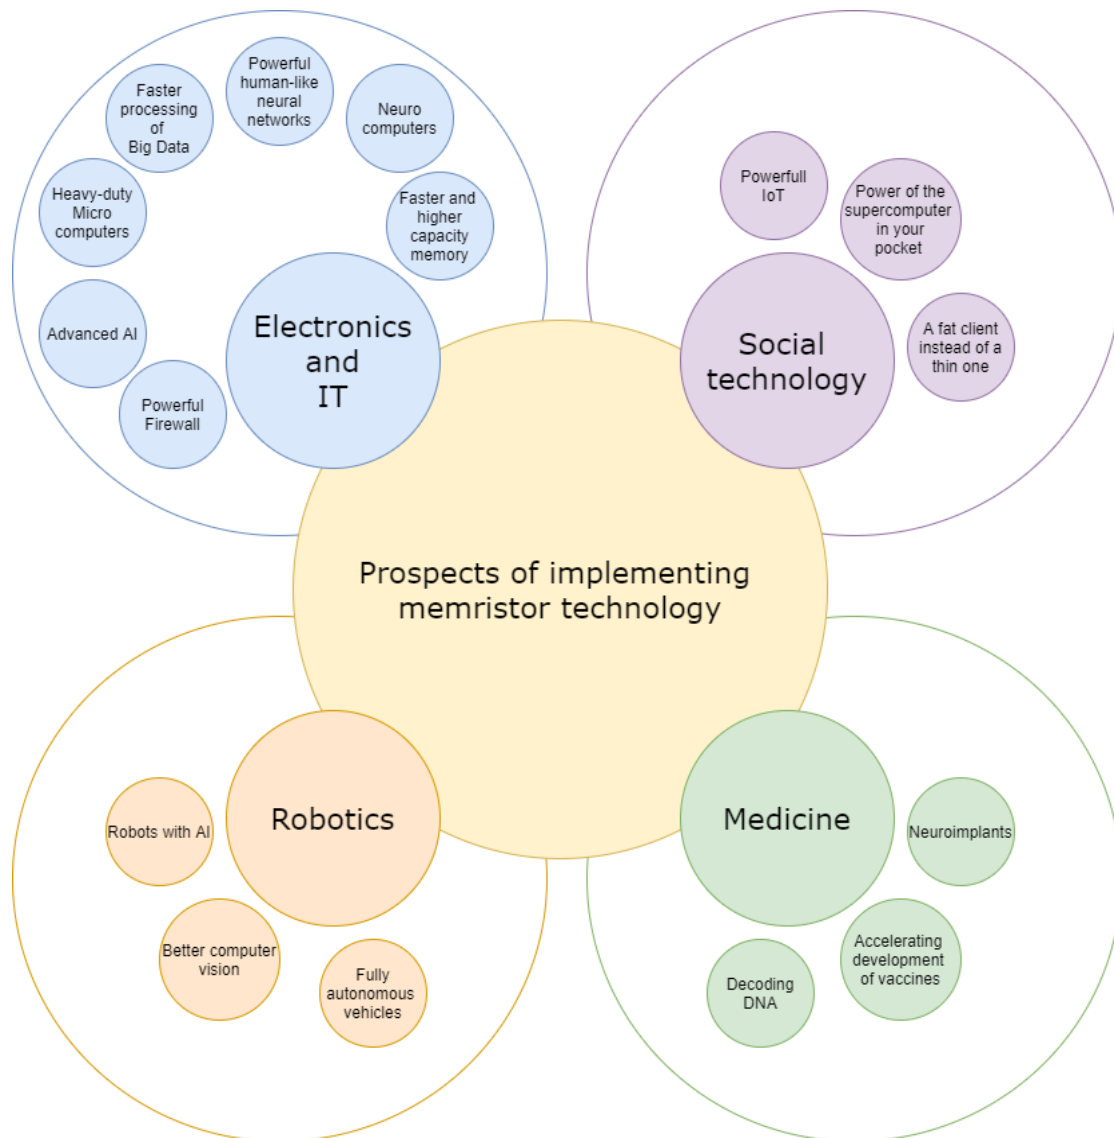
The effect of memristive technology on the development trends in modern smart systems is presented in Fig. 12. Memristive technology is versatile. In terms of manufacturing and IT, this technology will lend powerful impetus to the development of computer technology, forecasting and automation algorithms. In the field of social technology, the introduction of memristors can significantly improve the security of personal data (Halkos & Skouloudis, 2016; Metaxas, 2016). Implementing memristor technology in medicine will generate abundant resources for scientific research in the field of vaccines and diseases. Robotics will acquire genuine artificial intelligence that can simulate human behavior without using absolute algorithms, the variability of which is limited only by positive or negative values.


Fig. 12. Prospects of implementing memristor technology

The benefits of implementing memristive technologies, such as increased capacity and energy efficiency, will contribute to the development of Big Data. This will entail the expansion of CAD systems' capabilities while simulating the environment through creating digital twins (Vichugova, 2020).

The efficiency of the IoT is expected to rise, which will make it possible to decentralize increasingly complex mechanisms, and sensors will be able to track and transmit larger volumes of data. All devices can be synchronized within the same ecosystem and work as a single unit. Cloud storage and computing will become the crucial link between specialists in different fields, simplifying the introduction of changes and adjustments to the development and production process.

The similarity between the memristor and the synapse will make the next step forward in the field of neural networks and artificial intelligence. Neural computing productivity expanded massively will lead to even more

efficient machine learning, and computer "vision" will move far forward, which can significantly accelerate the development of robotics. Due to memristive technologies, artificial intelligence and synaptic neural networks will be able to get closer to the power, flexibility and variability of human brain. All the aspects mentioned above are a prerequisite for further development of smart systems.

Conclusions

The present paper has concentrated on the analysis of memristive technology. Having considered the available data, one can conclude that today's market of memristor-based devices is, in the first place, a market of ideas, research studies and patents. The research interest in memristors is constantly growing. Over the last decade, the number of publications on memristors has increased 8 times. The similar dynamics is observed among studies indexed in Web of Science, Scopus and eLIBRARY.RU. The obtained estimates show that the memristor market is highly competitive and is represented by a number of active players. The majority of companies expand their market presence by entering various end-user segments. The annual market growth rate will average about 80% and near USD 8.9 billion by 2024 and USD 13.5 billion by 2027. North America is among the strongest markets for memristors. This is due to significant investment in R&D from local market players, many of which are situated in the United States. However, in terms of the memristor technology implementation, it is only possible to make forecasts for the next 10 years, since many unsolved technological and economic problems still persist.

DEVELOPMENT OF PROXIMITY IN CLUSTER ORGANIZATIONS

Anna Maria Lis

Gdańsk University of Technology, Gabriela Narutowicza 11/12, 80-233 Gdansk, Poland

E-mail: Anna.Lis@zie.pg.gda.pl

Abstract. Sustainable development in cluster organizations (COs) is most fully manifested in the synergy effect. In turn, the synergy effect is achieved thanks to the development of proximity among cluster entities. The purpose of the paper is to test two conceptual models reflecting relations between selected dimensions of proximity in cluster organizations. The author reports the findings of a quantitative study conducted in four COs. The basic technique for collecting data was an online questionnaire. Both theoretical models were tested using Structural Equation Modelling.The research goes beyond the state-of-the-art knowledge in the concept of industrial cluster by exposing a broader view on cluster cooperation, which is developed on the basis of geographical proximity, and simultaneously contributes to the development of proximity in other dimensions: social, competence and organizational.

Keywords: cluster; cluster organization; cluster cooperation; proximity

1. Introduction

The review of theoretical concepts regarding the issue of cooperation among economic entities anchored in a specific location shows their strong connection with a broad understanding of the category of proximity. It turns out that regardless of whether Marshall's industrial districts or other theories perceiving the region as a hub of knowledge (including the cluster concept) are analyzed, each of these ideas uses elements directly related to the concept of proximity. This is important because without "proximity", many elements that make up the definitions of subsequent forms of the coexistence of economic entities operating in a given territory would be beyond the reach of influence of the entities managing them. As numerous studies show, proximity in various dimensions enables synergy to be achieved. According to Porter's approach, the cluster is a system of mutually related companies and institutions, and its value as a whole is greater than the sum of the values of its individual parts (Porter, 2008). Cooperation in clusters, based on geographical proximity facilitating the development of strong and lasting interactions within the cluster leads to the synergy effect, which is the basis for the sustainable

development of the cluster and its constituent entities, but also for the region in which the cluster operates. Porter clearly emphasizes the competitive advantage of clusters, claiming that cooperation in clusters has a positive effect on increasing the efficiency, innovation and entrepreneurship of the enterprises operating in clusters. Despite the accompanying competition risk, cluster cooperation could therefore be considered as one of the forms of modern entrepreneurship that could help in the sustainable development of enterprises, especially those representing the SME sector (Havierniková & Kordoš, 2019). "Proximity" provides a specific concretization of the features, processes and mechanisms underlying the business activity of entities, and thus facilitates their understanding, increasing the possibility of effective management. The knowledge of proximity and its dimensions, as well as the ability to apply it in practice, therefore, seems to be extremely important for the management of both individual enterprises and groups of enterprises associated in higher-order organizations, including cluster organizations (COs).

Meanwhile, the concept of proximity, although cognitively attractive, is still a scarcely explored area in management sciences. The literature especially lacks publications that would connect the concept of proximity with cluster organizations (not clusters). As a result of a systematic review of the literature, no publication was found that would associate different dimensions of proximity with COs. In the databases (Web of Science Core Collection and Scopus), only publications combining the issue of proximity with the concept of clusters were found (e.g. Yamada & Kawakami, 2015; Levy & Talbot, 2015; Bahlmann, 2016). This is also due to the fact that most publications in scientific literature refer to clusters viewed in geographical or economic categories, yet only a few of them address clusters as organizations. Insufficient recognition of the issues related to the development of cooperation in COs, and their poor description in the literature as well as the lack of publications combining the concept of COs with the concept of proximity, which is a visible juxtaposition regarding the dynamic development of these structures in the world, indicate a huge cognitive, research and methodological gap.

The paper reports the findings of a quantitative study based on an analysis of four COs from the metal and the ICT industries in Poland concerning the dynamics of proximity and its role in the development of cooperative relationships in COs. The study presented in this paper should be considered as a continuation of the author's earlier study on the development of proximity in COs, in which priority was given to qualitative research (Lis, 2018). The aim of the current study was to test two research hypotheses formulated as part of the concept of proximity, developed on the basis of the qualitative research, reflecting the relations between the individual dimensions of proximity in COs.

The research goes beyond the state-of-the-art knowledge in the concept of industrial clusters (with a particular emphasis on cluster organizations) by exposing a broader view of cluster cooperation, which is, on the one hand, developed on the basis of specific dimensions of proximity (especially geographical proximity), and on the other, contributes to the development of proximity in other dimensions. Although the study was conducted in Poland, it offers findings that may be verified in other countries, especially those in the EU where cluster policies are implemented, focused on cluster development by means of COs.

The paper is organized in the following manner. Firstly, the paper contains a literature review on proximity, and its dynamics and connection with industrial clusters. Secondly, it includes details with regard to the methodology: conceptual assumptions and research hypotheses, operationalization, the research sample, and the techniques for collecting and analyzing data. The third part reports the empirical results. Finally, there is a discussion, followed by conclusions with the study contributions, limitations and directions for future research.

2. Literature review

2.1. Proximity and its dimensions

The use of "proximity" for scientific research and analysis in the economic field began to gain popularity at the end of the twentieth century. Since then, more and more scientific works on this issue have been produced. According to the latest systematic review of the literature, around 2,8 thousand papers on proximity are identified in the Web of Science Core Collection database, whereas in the Scopus database this number is even higher (almost 4,000). In the 1980s and early 1990s, the literature on proximity was dominated by an approach that concentrated on the relationships within an organization (Monge et al., 1985; Rice & Aydin, 1991). Since the mid-1990s, the focus of attention shifted to the inter-organizational context of proximity (Klimas, 2011; 2020). The development of the concept of "proximity" as well as its dissemination in the literature was largely influenced by the French school of proximity (Rallet & Torre, 1999; Gilly & Torre, 2000; Torre & Rallet, 2005), emphasizing that proximity is the key element in the process of coordinating economically oriented activities. It facilitates the transfer of knowledge, improves the mechanisms of providing strategic information and has a positive effect on conflict resolution (Boschma et al., 2014). In addition, proximity is considered to be a factor that significantly improves the processes of cooperation among entities (Petruzzelli et al., 2009), reduces uncertainty in relationships (Boschma, 2005a; Paci et al., 2014) and remains conducive to the development of innovation.

The term "proximity" is merely a common term that refers to a set of specific aspects; however, the list of these aspects is neither complete nor unambiguous. Researchers most often refer to the five dimensions of proximity proposed by Boschma: geographical, cognitive, social, organizational and institutional proximity (Boschma 2004; 2005a; 2005b; Boschma & Frenken, 2010; Boschma et al., 2014; Balland et al., 2015). In terms of the number of publications in the above-mentioned databases referring to individual dimensions of proximity, geographical proximity takes first place. Second place is occupied by social proximity, followed by organizational then cognitive proximity, with the institutional dimension at the end of the list (Lis, 2018).

Geographical proximity is characterized by slight ambiguity (Knoben & Oerlemans, 2006). Relatively, the most common understanding of geographical proximity is Boschma's definition, according to which it is defined as the physical distance between actors, and this distance can be understood as a distance measured in specific units or as the time necessary to move from point A to point B (Boschma et al., 2014; Boschma, 2005a). Social proximity refers to relationships among entities, characterized by the trust created due to at least one of the following reasons: kinship ties, bonds of friendship, ties based on the past, personal experience connecting the analyzed entities (Boschma, 2005a; Heringa et al., 2014; Broekel & Boschma, 2012). The positive impact of social proximity on the results of cooperation among entities has already been quite well described in the literature, with a particular emphasis on the impact of relationships on the exchange of tacit knowledge (Boschma, 2005a; Boschma et al., 2014; Doloreux, 2002) and higher innovation (Tremblay et al., 2003; Paci et al., 2014; Guerini et al., 2013), and therefore factors that can be associated with cognitive proximity. The most general understanding of cognitive proximity indicates that this term is simply the similarity in the processes of receiving, interpreting, understanding and assessing the world (Wuyts et al., 2005). Cognitive proximity can also be understood as the degree of convergence of the knowledge systems of the analyzed entities. The importance of cognitive proximity manifests itself in many issues, but the key aspect to which this dimension of proximity applies is the process of knowledge exchange and creation. It is an element necessary for the proper functioning of communication processes and knowledge transfer mechanisms, as it enables the accurate identification, proper interpretation and effective use of new elements in the knowledge system (Cohen & Levinthal, 1990). The designations of the last two identified dimensions of proximity – organizational and institutional – overlap to a large extent, but maintaining the separateness of these categories allows their characteristic features to be captured. Using the existing understanding of organizational proximity (Knoben & Oerlemans, 2006; Boschma, 2005a; Boschma et

al., 2014), it can be defined as the suitability of two or more organizations in terms of both the logic of similarity (e.g. the similarity of internal structures and processes, the degree of inter-organizational dependencies) and the logic of belonging (sharing a specific space of relations, e.g. in participation in the same higher-order organizations as the CO). In turn, most approaches to institutional proximity are based on the concept of "institution" proposed by North (North, 1990). This dimension of proximity can be understood as the degree of overlap between the formalized elements of normative order (legal provisions and administrative requirements in force in a given area) and the informal system of values, thinking and behavioral patterns within which the analyzed entity and the entities associated with it operate.

2.2. Dynamics of proximity

A characteristic feature of each of the created proximity dimensions is their dynamic nature. The static perspective gives "proximity" primacy over relationships, while in the dynamic perspective, the analysis focuses on conditions in which "proximity" becomes the source of relationships or the relationships produce "proximity". There is no dimension of proximity that would function in perfect isolation from the other dimensions. This means that the dynamics of a particular aspect of proximity are influenced not only by what happens within that particular aspect, but by anything that occurs in each of the other dimensions. The dimensions of proximity create a structured system in which each element is related to the others, and the changes occurring in one part of the system affect different areas with different strengths. From the point of view of dynamics, it is also important that each of the dimensions of proximity differs from the others not only in the nature of the relationships it describes, but also in a certain "susceptibility" to change. This means that some of the dimensions of proximity are much more flexible (they are more often and easily changed), while others react with a delay and a smaller scope of introduced modifications. The literature review shows that the dimension relatively the most prone to change is social proximity (Dosi & Nelson, 1994), and the hardest to change, relatively, is the geographical dimension (Stam, 2007).

Geographical proximity is a unique dimension of proximity, especially in the context of COs. This is the most difficult to modify, but also the most basic and earliest recognized type of proximity. Geographical proximity can stimulate other dimensions of proximity, and is often replaced by them (Boschma, 2005a). Geographical proximity, although not a prerequisite for the establishment of cooperative relationships among economic entities, may act as a factor supporting the formation of such relationships in other aspects of proximity. The effect of a physical "neighborhood" will almost always contribute to the formation of a specific "overlay" between the spatial dimension of proximity and its other dimensions (Malmberg & Maskell, 2006). This applies especially to proximity in the social dimension (Hansen, 2015). However, this is not obvious in the case of cognitive and organizational proximity, which have the feature of the substitutability of geographical proximity. Geographical proximity can strengthen cognitive proximity (Paci et al., 2014; Guerini et al., 2013; Boschma, 2005a). This gains importance especially in cases where establishing cooperation is accompanied by a low level of cognitive proximity among potential partners. With a high level of cognitive proximity, however, the relevance of geographical proximity significantly decreases (Singh, 2005). Compatible knowledge bases of cooperating entities allow effective cooperation even when the involved partners are significantly distant from each other (Hansen, 2015). Geographical proximity is not a catalyst for processes of the constitution and strengthening of organizational proximity – both in its intra- and inter-organizational dimension. In addition, when organizational proximity reaches a high level, i.e. when there is a detailed and precise division of tasks within the organization, coordinated by a strong, central core and partners share common experiences (an element of cognitive proximity), the need to be in geographical proximity may disappear (Rallet & Torre, 1999).

The lack of common ground resulting from the nature of the location of the enterprise may act as a brake on the development of emerging or already established cooperative relationships. Too low a level of geographical proximity characterizing relationships among entities means the lack of a certain group of common conditions

determining the nature of their activities. However, too large a level of geographical proximity may have an equally negative impact on the activities of cooperating enterprises (Malmberg & Maskell, 1997; Boschma, 2005a).

2.3. Proximity in industrial clusters

The concept of proximity can be superimposed on the concepts developed so far in the literature of the cooperation of economic entities embedded in a specific territory, which all emphasize the inseparable link between geographical proximity and other dimensions of proximity.

The vision of the industrial district is an example of an almost complete approach to the issue of synergies occurring among business entities (in terms of the scope of including factors related to various dimensions of proximity). In Marshall's industrial districts (Marshall, 1890), as in the Italian industrial districts (Pyke et al. 1990; Becattini 2002; Bellandi, 2002; Sforzi, 2002), next to the obvious connections between the concept of the district and geographical proximity, threads can be seen highlighting the importance of other dimensions of proximity. The different dimensions of proximity: cognitive (knowledge spillovers, the similarity of entities in terms of their set of competences and used technology, as well as their complementary diversity), social (relatively stable relationships among entities), organizational (phases and technically divisible production processes implemented in the cooperation of entities) and institutional (anchored in the local system of values and norms) play the role of pillars in the industrial district arising from the foundation of geographical proximity. The group of theories of regional development based on knowledge and innovation (Martin, 2003) are focused to the greatest extent on the threads which emphasize the role of cognitive proximity (appearing primarily in the context of innovation and pro-innovation activities), which does not mean, however, that they ignore the role of other dimensions of proximity. Nevertheless, each of these concepts emphasizes a different dimension of proximity. Cognitive proximity plays a key role in the concept of the learning region (Florida, 1995; Asheim, 1996; Morgan, 1997). This concept puts special emphasis on the mechanisms and processes responsible for the relative overlap of the competency sets of entities operating in a specific area. The concept of the innovative milieu (Aydalot, 1986; Camagni, 1991; Maillat, 1998) emphasizes social and institutional proximity – that is, networks of informal social contacts based on trust, developing on a common socio-cultural basis. A similar accent can be found in concepts emphasizing the systemic dimension of innovation: regional innovation system RIS (Braczyk et al. 1998; Cooke 2001; Doloreux & Parto, 2005) or innovation ecosystem (Adner, 2006; Autio & Thomas, 2014). They pay attention to the role of institutions and the relations among actors – in the RSI concept, the links between entities (social and organizational proximity), and the processes of generating and diffusing knowledge (cognitive proximity) are spotlighted, but additional emphasis is placed on the culture and institutions which determine the cooperation of entities (connected to institutional proximity). In the innovation ecosystem concept, proximity appears primarily in the organizational (the division of work among organizations based on their specialization), cognitive (the complementarity of knowledge and skills) and social (the interrelationships of system components) dimensions, while the rank of geographical and institutional proximity is slightly lower compared to the other discussed concepts.

In the cluster concept developed by Porter (1998; 2000; 2008), individual dimensions of proximity can also be highlighted. Already through the very definition of the cluster, Porter linked threads of geographical proximity (a geographical cluster of entities of various types), organizational proximity (the fact of participation in the same higher-order structure), social proximity (the simultaneous cooperation and competition of the entities forming the cluster), cognitive proximity (the similarity of competences related to belonging to the same sector) and institutional proximity (broadly understood as the cultural and administrative bases for conducting business by the entities involved in a given cluster). However, cluster organizations are separate entities and cannot be identified with clusters. They should be understood as formally established organizations which function at a higher level of aggregation, are composed of institutional members that have joined them purposefully, and act actively in order

to achieve some collective or individual objectives (Lis, 2018). Cluster organizations, also referred to in the literature as bottom-up clusters or cluster initiatives, are focused on supporting the development of a given cluster (Sölvell et al., 2003; Lindqvist et al., 2013). Due to the obvious connotations with the cluster (the CO concept has grown on the foundations of the cluster concept), the CO is based on similar types of proximity (primarily, the geographical and institutional dimensions), although they may be slightly differently shaped (this applies especially to proximity in the social, cognitive and organizational dimensions). The differences between the cluster and the cluster organization can also be manifested in the relationships occurring between individual dimensions of proximity.

3. Methodology

3.1. Conceptual assumptions

The qualitative research on which the current research is based was conducted by Lis in 2016. As a result of this prior research, two theoretical concepts were generated (Lis, 2018). These concepts are interrelated, hence they can be treated as one coherent theoretical concept, allowing for a better understanding and explanation of the mechanisms of cooperation in COs. The first concept covers the trajectory of the development of cooperative relationships in COs, while the second one concerns the development of proximity in such organizations. As part of the first developed concept, four main levels of cluster cooperation were identified, with regard to "the main objectives", indicating the key type of activity in COs (Tab. 1). The second concept, raised to a higher level of abstraction and applied to the first concept, explains how proximity can support the development of cooperation in COs. The research results have proved that different dimensions of proximity strongly affect every single identified level of cooperation. In turn, cooperation at every level causes the development of proximity in various dimensions. This is reflected in the objectives defined at individual levels of cooperation that correspond to different types of proximity, and therefore their achievement may mean the development of proximity in a specific (assigned to a given level) dimension. In Table 1, each level of cooperation has been assigned defined objectives and dimensions of proximity have been identified at the entry and exit levels.

Table 1. Levels of the development of cooperation in cluster organizations

Level number	Level name	Main objectives	Proximity: entry	Proximity: exit
I	"Integration at the unit level"	1. Creating a base network of relationships among cluster partners	– Geographical, competence – Competence proximity (in terms of the scope of competence)	– Social proximity
II	"Allocation and integration at the process level"	2. Facilitating access to the increased pool of resources, including information 3. Increasing the quality of products and services and / or reducing the business costs	– Competence proximity (in terms of the scope of competence)	– Competence proximity (in terms of the level of competence development) – Organizational proximity
III	"Impact on the environment"	4. Gaining impact on the external environment of the organization	– Geographical, competence – Competence proximity (in terms of the scope of competence)	– Institutional proximity
IV	"Creation and integration at the organizational level"	5. Setting up conditions to create common added value by pooling resources	– Social proximity – Competence proximity (in terms of the scope of competence) – Competence proximity (in terms of the level of competence development)	– Social proximity – Competence proximity – Organizational proximity

121

All the conceptual categories used to create both generated concepts were based on the conducted qualitative research. The individual elements of the concepts were therefore not a preconceived idea, but constituted the best theoretical explanation of the tendencies observed from the qualitative research in the analyzed organizations. The identified dimensions of proximity basically coincided with the classic Boschma division (2004; 2005a; 2005b), with the exception of cognitive proximity. The results of the empirical research showed that – in need of a better explanation of the development of cooperation in the studied COs – it would be necessary to slightly differentiate proximity in this dimension. Based on the research, it could be seen that the relationships among cluster entities were shaped differently when their similarity was visible in the scope of their competences, and differently when this similarity related to the level of advancement of these competences. The above observation led to the distinction of a completely new dimension of proximity: "competence proximity" (taking into account both the scope of competences and the level of competence development) in place of "cognitive proximity".

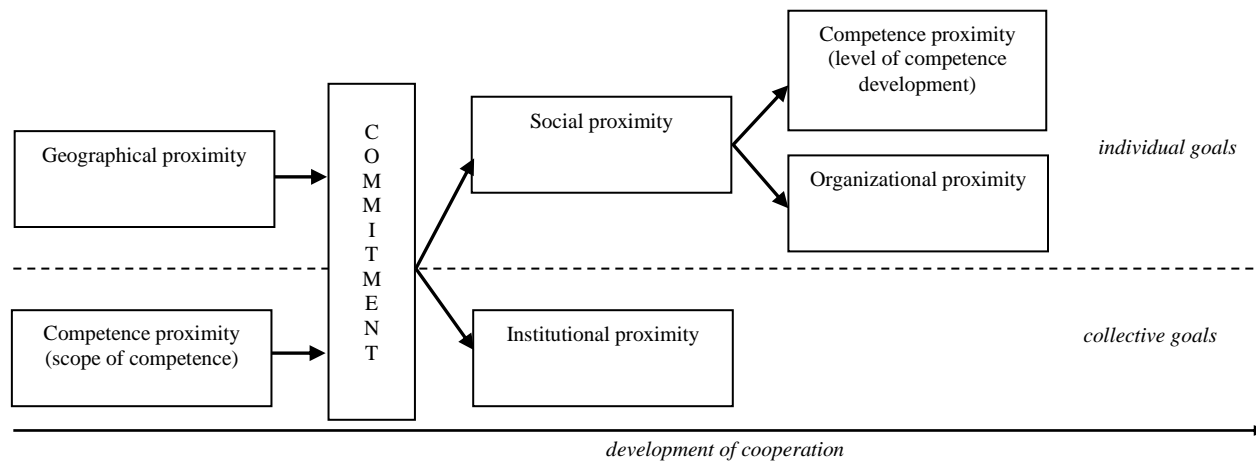
Moving along the developed trajectory for the development of cooperation in COs (going from level I to level IV), relationships among different types of proximity were identified: the development of cooperative relationships in COs is determined by geographical and competence proximity (in terms of the scope of competences), on the basis of which (with the commitment of cluster entities) social and institutional proximity are developed, followed by competence proximity (in terms of the level of competence development) and organizational proximity (Fig. 1). In the developed model, in addition to proximity in various dimensions, an additional variable emerged on the basis of the qualitative research: the commitment of cluster members in activities undertaken as part of the CO.


Figure 1. Links between dimensions of proximity

Source: Lis, 2018.

3.2. Research hypotheses

The combination of levels of cooperation with the specific proximity dimensions expected at the "entry" and "exit" of a given level, with linking together the identified dimensions of proximity, allows the analysis of proximity in dynamic terms. This gives rise to the formulation of two research hypotheses (additionally divided into constituent hypotheses), reflecting the complex nature of the cause-effect relationships occurring between selected dimensions of proximity in COs (Table 2). The H1 and H2 hypotheses focus only on three successive

levels (I, II, IV), best illustrating the development of cooperation in COs. The hypotheses do not take into account level III, referring to the relationships among cluster members and external entities (from outside the CO). The qualitative research shows that institutional proximity (responsible for achieving objectives at level III) plays an insignificant role in the development of inter-organizational cooperation.

Table 2. Research hypotheses

Research hypotheses	Constituent hypotheses
H1. Social proximity created on the basis of geographical proximity has a positive impact on the development of competence proximity (in terms of the level of competence development) and organizational proximity.	H1.1. Geographical proximity has a positive effect on the development of social proximity.
	H1.2. Social proximity has a positive impact on achieving the objectives directly related to the development of competence proximity (in terms of the level of competence development) and organizational proximity.
	H1.3. Social proximity has a positive impact on gaining access to information and knowledge, determining the development of competence proximity (in terms of the level of competence development).
	H1.4. The achievement of the objectives directly related to the development of competence proximity (in terms of the competence development level) and organizational proximity positively affects the access to information and knowledge.
H2: Geographical proximity is important for the constitution and development of a cluster organization because it has a positive impact on the commitment of cluster members, which – in turn – has a positive impact on the development of social proximity.	H2.1. Geographical proximity has a positive impact on the commitment of cluster members.
	H2.2. The commitment of cluster members has a positive impact on the development of social proximity.

Source: Lis, 2018.

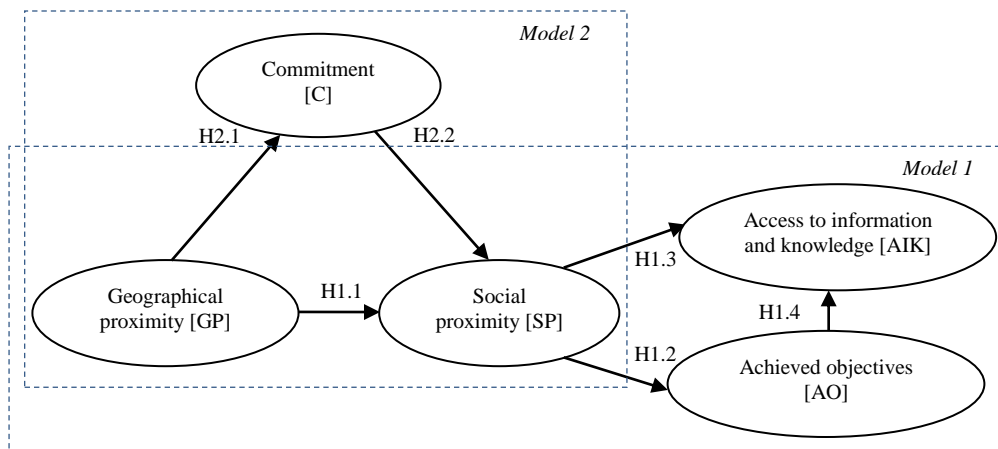
The relationships described in the form of the H1 and H2 hypotheses form two multidimensional conceptual models, tested in this paper (Fig. 2) (the separation of the H1 and H2 hypotheses was due to conceptual and methodological reasons).


Figure 2. Conceptual models
Source: Lis, 2018.

3.3. Operationalization

The latent variables used in both models were operationalized by selecting the appropriate observable indicators, and additionally using exploratory factor analysis. An ordinal scale (5-point Likert scale) was used to measure the variables. In Model 1, a total of 4 latent constructs were used, described using 15 observable indicators. To measure geographical proximity [GP], three variables were used to refer to the physical distance among cluster entities. Social proximity [SP] was described by three variables showing the process of creating bonds among cluster members: starting from the development of relationships, through trust building, to the verification of trust based on the experience of cooperation. Another variable – achieved objectives [AO] – in the proposed conceptual model was reduced to three objectives directly related to the development of competence proximity (objective 1 – corresponding to level II) and organizational proximity (objective 2 – level II, objective 3 – level IV). The last variable in the model – access to information and knowledge [AIK] (determining the development of competence proximity in the discussed aspect) – was described using six observable variables.

Model 2 uses 3 latent constructs (described using in total 14 observable indicators): geographical and social proximity (appearing in Model 1) and commitment [C], measured on the basis of eight observable variables corresponding to individual levels of cooperation in COs (the two most characteristic forms of commitment for each level).

3.4. Research sample

The research was carried out in 2017 in four purposefully selected cluster organizations in Poland. The same COs that participated in the earlier qualitative research (2016) were selected for the quantitative research. In the selection of COs the extreme cases approach was used to ensure maximum variability and diversity within the research field. Taking the economic sector as the main differentiating criterion, the research was conducted in two COs representing the ICT industry (Mazovia Cluster ICT [MC ICT] and Interizon: Pomeranian Region ICT Cluster) and two from the metal industry (Metal Cluster of Lubuskie Province [MCLP] and Metal Working Eastern Cluster [MWEC]).

The surveyed cluster organizations are formal organizations that were launched at a similar time (in the period 2007-2009). They also have a similar, regional scope of activity. However, they differ in the way they were established. All four COs wre created as a result of a large involvement of the enterprises, but only one of them (MCLP) is considered a bottom-up initiative, while the other three are mixed forms. In addition, COs representing the ICT sector are much larger than metal COs (the number of members in the studied COs in the analyzed period was: MCLP – 35, MWEC – 78, MC ICT – 200, and Interizon – 130). The research covered 132 cluster enterprises: 51 from metal COs (38 from MWEC and 13 from MCLP) and 81 from ICT COs (45 from MC ICT and 36 from Interizon).

3.5. Techniques for collecting and analyzing data

The basic technique for collecting data was an online questionnaire. Both theoretical models were tested using structural equation modeling. In the analysis, the two-step sequential approach of Anderson-Gerbing (1988; 1992) was used. Exploratory factor analysis and confirmatory factor analysis were used to test measurement models. Both analyses were performed using the maximum likelihood estimator and were based on the value of the KMO (Kaiser-Meyer-Olkin) measure of sampling adequacy. After testing the validity of the measures of the measurement models, structural models were constructed and all dependency paths in these models were analyzed, which allowed the research hypotheses to be tested.

4. Research results

4.1. Model 1

In the case of Model 1, exploratory factor analysis showed a very large fit of observable variables to latent constructs (the value of the KMO measure of sampling adequacy was 0.818, Bartlett's sphericity test was statistically significant, p <0.001). The main analysis used to verify the conceptual model was, however, confirmatory factor analysis (CFA). The value of χ^2 was 150.25 (DF = 84), while the value of CMIN / DF was 1.79. The RMR was achieved at an acceptable level of 0.07, as was the RMSEA approximation error, which reached 0.078 (which is within the acceptable limits, but within the upper limit for a good fit). The CFI and TLI exceeded the minimum 0.9 values adopted for well-matched models (Table 3).

Table 3. Confirmatory factor analysis results for Model 1

Variables	Cronbach's α	CR	AVE	Correlations between variables			
				[GP]	[SP]	[AO]	[AIK]
Geographical proximity [GP]	0,83	0,85	0,67	0,82			
Social proximity [SP]	0,77	0,78	0,54	0,28	0,73		
Achieved objectives [AO]	0,82	0,82	0,6	0,11	0,26	0,77	
Access to information and knowledge [AIK]	0,91	0,91	0,64	0,17	0,7	0,44	0,80

χ^2=150,25 (DF=84); CFI=0,94; TLI=0,92; RMSEA=0,078 (90%CI=0,057–0,097); RMR=0,07; CMIN/DF=1,79; AIC=222,25; *n*=132

Source: the author.

The standardized value of factor loadings of all adopted observable variables exceeded 0.5, and the vast majority (except for [GP3] and [SP3]) also 0.7 (all factor loadings were also statistically significant, p≤0.001). The AVE indicator calculated for each latent variable exceeded the recommended value of 0.5. The reliability measures: Cronbach's α and CR for each construct exceeded the limits of 0.7. All of the fit and convergence indicator values used exceeded their acceptability thresholds (Hair et al., 2014), which decided on the measurement model to adopt for the structural modeling process.

A structural model was then built in which the interaction between latent variables was assessed. Based on the conducted analysis, it was determined that Model 1 achieved the recommended degree of fit (Table 4).

Table 4. Path analysis results for Model 1

Hypotheses	β	t	p	Acceptance/ rejection
H1.1. Geographical proximity [GP] –> Social proximity [SP]	0,27	2,53	0,011	A
H1.2. Social proximity [SP] –> Achieved objectives [AO]	0,27	2,44	0,015	A
H1.3. Social proximity [SP] –> Access to information and knowledge [AIK]	0,62	5,35	0,000	A
H1.4. Achieved objectives [AO] –> Access to information and knowledge [AIK]	0,28	3,23	0,001	A

Legenda: χ^2=150,58 (DF=86); CFI=0,94; TLI=0,93; RMSEA=0,076 (90%CI=0,055–0,095); RMR=0,07; CMIN/DF=1,75; *n*=132

Source: the author.

The analysis of the paths did not give rise to the rejection of the H1.1-H1.4 hypotheses (all four paths proved to be statistically significant). It was established that geographical proximity had a positive impact on social proximity, which supported the H1.1 hypothesis. Social proximity had a positive impact on the achieved objectives, related – in this case – to competence proximity (in terms of the level of competence development) and organizational proximity, which in turn supported the H1.2 hypothesis. The very high β value associated with the H1.3

hypothesis supports the argument about the strong positive impact of social proximity on access to information and knowledge. It was also confirmed that the achieved objectives had a positive impact on access to information and knowledge in the studied COs (support for the H1.4 hypothesis), which contributed to the further development of competence proximity (in the indicated aspect).

4.2. Model 2

In the case of Model 2, exploratory factor analysis also showed a large fit of the developed constructs (KMO = 0.861, the Bartlett sphericity test was statistically significant, p <0.001). Based on confirmatory factor analysis, the initial model was slightly modified. Modification indexes have shown that it is worth correlating the latent residual variables in the construct "commitment" [C] (due to the high covariance values: e4 with e5, e5 with e9, e10 with e11). This allowed the model to be improved to fit to the planned constructs in accordance with the made assumptions[*]. After the above modification, the values of all indicators adopted for analysis fit within the recommended ranges: $\chi2$ - 123.18 (DF = 71), CMIN / DF – 1.73, RMR – 0.061, RMSEA – 0.075. The incremental fit indices were higher than 0.9: CFI reached 0.96 and TLI reached 0.95 (Table 5).

Table 5. Confirmatory factor analysis results for Model 2

Variables	Cronbach's α	CR	AVE	Correlations between variables		
				[GP]	[C]	[SP]
Geographical proximity [GP]	0,83	0,85	0,67	0,82		
Commitment [C]	0,93	0,93	0,64	0,34	0,80	
Social proximity [SP]	0,77	0,78	0,54	0,27	0,60	0,73

χ^2=123 (DF=71),18; CFI=0,96; TLI=0,95; RMSEA=0,075 (90%CI=0,052–0,097); RMR=0,061; CMIN/DF=1,73; AIC=191,18; *n*=132

Source: the author.

Tests on the accuracy of the proposed model were also successful: standardized factor loadings reached values higher than the acceptable level of 0.5, and almost all (with the same exceptions as in the first model, i.e. [GP3] and [SP3]) exceeded the minimum level of 0.7. For each latent variable, the AVE index value was over 0.5, while the values of Cronbach's α and CR coefficients were at a level exceeding the minimum threshold of 0.7. The positive assessment results of the measurement model allowed for its adoption to the next stage – structural equation modeling.

In the next step, an assessment of the interaction between latent variables was carried out, which allowed the research hypotheses to be tested. The analysis showed a good fit of the model (Table 6).

Table 6. Path analysis results for Model 2

Hypotheses	β	t	p	Acceptance/ rejection
H2.1. Geographical proximity [GP] –> Commitment [C]	0,34	3,66	0,000	A
H2.2. Commitment [C] –> Social proximity [SP]	0,60	5,84	0,000	A

χ^2=123,93 (DF=72); CFI=0,96; TLI=0,95; RMSEA=0,074 (90%CI=0,051–0,096);RMR=0,064; CMIN/DF=1,72; *n*=132

Source: the author.

---

[*] The values of the indicators before the modification were: χ^2=186,23 (DF=74); CFI=0,91; TLI=0,89; RMSEA=0,11 (90% CI=0,088 – 0,127); RMR=0,067; CMIN/DF=2,52; AIC=248,23; *n*=132.

The path analysis did not give grounds for rejecting the hypotheses H2.1-H2.2. The β value associated with the H2.1 hypothesis confirmed the statistically significant, positive impact of geographical proximity on the commitment manifested at all identified levels of cooperation in the COs. In turn, the commitment had a statistically significant, strong, positive impact on the development of social proximity, which supported the H2.2 hypothesis. This means that an increase in commitment in the activities within a CO will result in the development of relationships among cluster partners and vice versa – a decrease in involvement will weaken those relationships.

5. Discussion

Both conceptual models – Model 1 (based on the H1 hypothesis) and Model 2 (described by the H2 hypothesis), proved to be valid under the conditions of the study. The relationships between variables reflected in Models 1 and 2 show the development of proximity in a CO. Geographical proximity is conducive to the development of social proximity, taking into account the commitment factor. The short distance among cluster entities enables involvement in activities undertaken at various levels of cluster cooperation (I-IV), manifested through the personal contact of persons representing cluster members, which in turn leads to the development of increasingly stronger relationships within the CO. This in turn causes the development of competence proximity (in terms of the level of competence development) and organizational proximity. This means that as the distance among cluster entities decreases, the potential for developing relationships among them (social proximity) increases, which consequently increases the similarities in the competence systems of these entities in terms of their levels of competence (competence proximity, in the analyzed aspect) as well as in their internal structures and the existing degree of inter-organizational interdependencies (organizational proximity).

The obtained research results therefore support the thesis regarding the primacy of geographical proximity over other dimensions of proximity, but at the initial stages of the development of cooperative relations in COs. Geographical proximity turns out to be the most fundamental dimension in initiating cluster cooperation because it provides the basis for the formation and development of proximity in other dimensions. However, along with the gradual transition to higher levels of cooperation, the importance of a common location for the effects of cooperation undertaken by cluster enterprises decreases. This causes a decrease in the rank of geographical proximity, giving way to other dimensions of proximity, especially social and competence (in terms of the level of competence development) dimensions, which increase as a result of developing relationships that guarantee better access to resources, primarily to knowledge and information. At the highest level, to undertake the most advanced forms of cooperation, leading to the gradual organizational integration of cluster partners (and thus the development of organizational proximity), a high level of trust and a high, and at the same time, very similar level of competence among the cooperating entities are already required. Therefore, the higher the level of cluster cooperation, in conjuction with the development of proximity in the social, cognitive, and organizational dimensions, the greater the synergy effect resulting from this cooperation, and thus the sustainable development of the entire cluster structure can be.

Conclusions

The connection of the very current contemporary issue of clustering within the extremely rarely undertaken aspect of cluster organizations with the concept of proximity has no equivalent in the literature. Since no similar publications have been found in the existing literature combining the issue of proximity with the concept of the cluster organization (or cluster initiative), it is impossible to find scientific publications that would simultaneously address the three issues mentioned above: (cluster organizations – the development of cooperation – proximity). Relying on four COs representing two very different sectors of the economy, and using them to test the relationships between the four dimensions of proximity selected from among the five identified in the previously

conducted qualitative research significantly enriches the existing achievements in the area of the discussed issues. In addition, the results of the research take into account the assumptions regarding the dynamics of proximity. The reasoning behind combining the identified levels of cooperation in COs with the specific dimensions of proximity necessary "at the entry" and those arising or developing "at the exit" of each of these levels is an example of considering the dynamic aspect of proximity.

The empirical findings can also provide some practical implications for public authorities, cluster coordinators, as well as for cluster members. Politicians responsible for shaping cluster-based policy at various levels, taking care of sustainable cluster development, should launch instruments of cluster policy that would strengthen the development of proximity, especially in the cognitive and organizational dimension. This applies in particular to supporting innovation, because the lack of investment in innovation can lead to the process of decline of economic competitiveness (e.g. Bonetto et al., 2014), and event the declay of the whole cluster. In the case of cluster coordinators, the concern for sustainable development of partner cooperation within a cluster organization should be manifested in undertaking conscious and intentional activities leading to achieving ever higher levels of cooperation (from I to IV) and motivating cluster members to engage in these activities. Finally, cluster members, wanting to achieve the synergy effect resulting from cluster cooperation within the CO, should strive to create more or less informal relationships, which can translate into the development of proximity in other dimensions.

The research has three main limitations. The first limitation is the relatively small and not very diverse research sample. This, therefore, does not allow the findings to be generalized. Nevertheless, the applied logic of sample selection according to the extreme cases approach (the sector as a differentiating criterion) allows the thesis to be put forward regarding a wider universality of the discovered regularities. The second limitation is the subjectivity inscribed in the specifics of research conducted in the field of social sciences. This also applies to the quantitative research carried out in the proposed form. The problem of subjectivity in the study was partially solved, as the quantitative research was a continuation of the previously conducted qualitative research. Thus it can be considered a kind of triangulation of source data and research methods. The third limitation concerns the structural equation modeling used to test the hypotheses (H1-2). An important limitation is the size of the research sample adopted in the quantitative research because drawing conclusions based on the results of structural modeling is only possible if stringent methodological assumptions regarding sample size are met. There is no consensus on the minimum sample size in SEM – it is most often dependent on the complexity of the model (Hair, 2014; Anderson & Gerbing, 1988; 1992). The number of variables in the analyzed models in relation to the number of observations should not raise any objections, the more so in that both developed conceptual models were well fit and the defined variables proved to be reliable.

From the viewpoint of the replication of results, the research should be repeated on a representative, large, random sample, taking into account additional sectors of the economy, using the same measurement tools. This would allow the confirmation of theoretical constructs, and in the case of obtaining results consistent with those obtained in the conducted research – reveal the universality of the observed relationships. In future studies, it would also be necessary to carry out an estimation of mediation in both models (omitted in this paper). In Model 1, two variables can play the role of mediator: "social proximity" [SP] or "achieved objectives" [AO]; in Model 2 – "commitment" [C]. In order to increase the universality of the developed concept of proximity, it should also be considered to include new comparative groups in the research.

Abstract. Hospitals and other providers of health services are facing enormous pressure to reduce costs while providing better services for patients without lowering their quality. By utilising a two-stage dynamic Data Envelopment Analysis (DEA) approach, we explore whether there is a compromise between the production of services and the quality of services in the process of providing health care at the level of hospitals in Slovakia. While the first stage deals with the production efficiency of the hospitals, the second stage deals with the quality of service using patient-reported safety and satisfaction measures. The efficiency of hospitals in Slovakia is assessed, using hospital-level data from the database of INEKO for the years 2015 and 2018. In order to dynamically analyse the efficiency changes during the analysed period, the Malmquist index was used. The results revealed that overall technical efficiency increased over the analysed period. We can also see an increase within the service production division as well as service quality division. The results obtained represent a significant platform for the creators of health policy at the national level, and for the creators of the strategic regional health plans as a basis of continuous creation of mechanisms that are inevitable for providing a sustainable system of the Slovak health care at the regional level. The global threats of epidemics, such as COVID-19 pandemic, address the question of public health systems' sustainability, which enormously increases.

Keywords: Two-stage dynamic DEA; Service production division; Service quality division; Hospitals; Slovakia

---

1. Introduction

Sustainability of health care system is connected with a research of balance between supply and demand. Efficiency and effectiveness of the health care system represent a possible strategy in resolving the disparities between supply and demand of health care in a publicly funded health care system. It means the production of better health care that is funded by a set budget while preserving the quality of services. Monitoring and evaluation of effectiveness and financial efficiency of the health care system are long-term priorities of senior political representatives, and also of the general public and general population. The entire population, irrespective of age, race, sex and/or nationality is affected by the quality and available health care. Health care and health protection of citizens are enshrined in the constitutions around the world.

Consequently, this area reflects a human's quality of life. These aspects are related to the sustainability of health care systems, which is connected to intense technological development and subsequent increase in costs on health care as well as processes of demographic ageing (Megyesiova, Lieskovska, 2018, 2019). However, there are no concepts of health care systems' sustainability that would be known at the national or international level. It may be related to significant heterogeneity, complex health systems, and many other specificities, such as health policy, government strategies, processes of demographic ageing within a country, regional disparities in morbidity and mortality of the regions within a country, availability of health care, etc. (Bednarova et al. 2013; Bem et al. 2019). Thus, it is necessary to connect health care system sustainability with effectiveness, which may be regionally differentiated. Knowledge of these factors may help the creators of health policy to set appropriate supporting, stabilizing and regulatory mechanisms so, that the differences between regions and health facilities in quality and effectiveness of health care would be as low as possible (Predkiewicz et al. 2019). Also, the question of health system sustainability increases in the context of the COVID-19 pandemic, when the governments have started to search for solutions of providing health care system funding in such a crisis (Androniceanu, 2020).

The study's motivation is all of the above-mentioned coherent facts. It aims to research relationships between the production of services and the quality of services in the process of providing health care at the level of hospitals in Slovakia, and consequently, to evaluate the rate of differences between them.

2. Literature Review

Many international research studies deal with research on factors of health care systems' sustainability. These factors may have a different impact on a population and social systems in the individual countries (Syczygiel et al. 2014; Ucieklak-Jez et al. 2018); Du et al., 2020). For instance, Vandersteegen et al. (2015) researched the impacts of no-fault compensation on health care expenditures in their study, while the authors focused on the OECD countries. Also, this study states that it is essential to improve current medical practice systems, which are a significant factor that determines health care costs, as well as compensation systems in health care. Similarly, the role and influence of responsibility processes in health care are critical. De Meijer et al. (2013) research the factors of costs' division on health care and the impacts of their increase. The structure of their allocation influences the growth rate of health care costs in hospitals. The authors used the Dutch data of real health care costs, hospital registers and mortality databases to perform the research. In the conclusion of their study, the authors emphasize an expected and permanent increase of costs on health care in the hospital sector due to technological development.

Consequently, it should improve treatment, its financing costs and procedural complexity (human resources, infrastructure, etc.). Thus, the sustainability of public health systems becomes the main topic. In the studies of van Baal et al. (2012), Kuca et al. (2015), the authors examine health care system sustainability by means of the analysis of relationships between changes in the mortality rates and costs on health care per person. Also, the authors emphasize that the growth of health care costs per person may significantly depend on age. Karslsberg

Schaffer et al. (2015) state and highlight that the evidence of cost efficiency is rarely used in the local health care expenditure plans. The study results stress the differences in objectives between Health technology assessment (HTA) bodies and local health service decision-makers. Grembowski et al. (2010) researched a relation of the changes in expenditures per capita of local health departments (LHD) to 1990–1997 changes in mortality rates for Black and White racial/ethnic groups in the U.S. The LHD costs were related to absolute reductions in mortality for infants, blacks, and white females. However, these costs did not close black-white mortality differences for these groups. Schofield et al. (2013) examined the impacts on income, taxes, government support payments and GDP due to lost labour force participation. In the conclusion of their study, the authors provide interesting facts: individuals bear the economic costs of lost income in addition to the burden of the condition itself. However, the state impacts include loss of productivity from reduced workforce participation, lost income, taxation revenue, and increasing government support payments - in addition to direct health care costs. These findings are significant for policy creators, who create prevention programs to eliminate morbidity and mortality of the most serious and expensive diseases, because their underestimation may have fatal impacts on finances of health and economic systems of a country. Even Brandle et al. (2016) connect health care system sustainability with an excess capacity of advanced medical technologies in the hospital sector, which influences health care costs' increase. This finding is significant, especially for decentralized structures of health care provision. Consequently, the importance of research efficiency of health care systems in the individual countries is evident and inevitable to setup sustainability strategies of health care systems in the individual countries. Zimon et al. (2016) see possible problem also in the logistic distribution in hospitals, which inhibit to higher health care efficiency.

Our study focuses on the research of hospitals' efficiency in Slovakia, and it aims to research a compromise between the production of services and the quality of services in the process of providing health care at the level of hospitals in Slovakia. The important impact has also health insurance company which achieved a special place among financial institutions, as mentioned by Liberko et al. (2012) Data Envelopment Analysis (DEA) was used in the study. In recent years, this method is also widely used in other research areas, and it contributes to the formation of new modules that reflect on the complexity of decision-making processes. Many research studies evaluate its appropriateness while showing many application possibilities as well as limitations.

Avkiran (1999) points out that DEA is a non-parametric linear programming technique that calculates a comparison ratio of outputs to inputs for each unit, which is reported as a relative efficiency score. The efficiency score is usually expressed as a number between zero and one or 0 and 100%. A decision unit with less than one can be considered as inefficient compared to other units. Luo (2003) states that DEA is a formulation of linear programming that defines a non-parametric relationship between multiple outputs and multiple inputs. It identifies the efficiency frontier, which consists of the most efficient decision-making units (DMU). Efficient DMUs are units for which no other DMU or linear combination of DMUs can generate at least the same number of given outputs. According to Zimková (2014), the non-parametric DEA method makes it possible to create the efficiency frontier and evaluate the efficiency of the DMU. Conventional DEA models are designed to maximise the relative efficiency of each decision unit, provided that the relative efficiency scores obtained in this way for each decision unit are also feasible for all other decision units in the data set. Therefore, both reference points are identified, the relatively efficient units that define the efficiency frontier, as well as the internal points that are below the efficiency frontier. Due to its deterministic nature, the DEA method hypothesises that the DMU causes all deviations from efficiency. Nevertheless, there are some elements, such as the legislative framework, the level of competition, the impact of the crisis, which the company cannot control and which also affects the efficiency of the unit under investigation. According to Palečková (2015), the DEA model can be designed either to minimise inputs or to maximise outputs. Input orientation focuses on reducing the number of inputs while maintaining at least current output levels, while output orientation aims to maximise output levels without increasing input utilisation. The DEA measures the relative efficiency of a homogeneous set of DMUs using multiple inputs to produce multiple outputs. The DEA also identifies the sources and degree of inefficiency for each input and output concerning inefficient DMUs. It provides a means for comparing the efficiency of multiple DMUs to each

other based on multiple inputs or outputs. Saleh & Malkhalifeh (2013) state that DEA has been applied in many studies in various sectors of the economy. Conventional DEA models consider the system to be single-process. However, there are several so-called network approaches, which consider a system to be composed of different processes or phases, each of which has its inputs and outputs and intermediates between the various phases. Two-stage DEA models have higher discriminative power than conventional, single-process DEA. The main disadvantage is the need for more detailed data (i.e. at the process level) and the greater complexity of the resulting models, especially if some inputs or outputs are shared between processes. Ozcan (2014) pointed to the fact that in health care, services are produced by various departments that each contribute to the overall efficiency of the hospital. It is more so for those hospital systems where the individual hospitals and other networks such as physician practices, nursing homes, ambulatory surgery centres, and diagnostic centres may be part of the whole picture. Through the network DEA model, one can observe not only the efficiency of the health care facility but also its sub-unit efficiencies as its components. Network DEA models were first introduced by Fare & Grosskopf (2000), and their models have been extended by Tone & Tsutsui (2009) and others. The network DEA model extended by Lewis & Sexton (2004) presents a multi-stage structure as an extension of the two-stage DEA model. Also, Kao (2017) pointed to the fact that the system is usually composed of many subsystems operating interdependently. Conventional DEA only considers the inputs supplied to and the outputs produced from the system in measuring efficiency, ignoring its internal structure. As a result, the overall system may be efficient, even while all component divisions are not. More significantly, there are cases in which all the component divisions of a DMU have performances that are worse than those of another DMU, and yet the former still has the better system performance. With an eye on solving these problems, many ideas have been extended from the conventional DEA to build models to measure the efficiency of production systems with different network structures, which are referred to as network DEA. Consequently, for systems composed of interrelated divisions, managers need to know how the performances of the various divisions are evaluated and how they are aggregated to form the overall performance of the system. We are also able to analyse the relationship between the efficiency of a system and those of its component divisions when the systems being examined have different types of network structures. This relationship shows the extent to which the efficiency of a division impacts that of the system as a whole. The division with the most significant effect is the one to which more effort should be devoted so that the performance of the overall system can be raised more effectively. Grmanová (2013) says that gradually the need arose to compare the efficiency not only of the whole process but it was also necessary to find out the efficiency of partial processes, into which this whole process is decomposed. It was the reason for the creation of two-stage DEA models. A two-step DEA can be used to evaluate the efficiency of the whole process, but also to examine the effectiveness of sub-processes. The use of a two-stage DEA method makes it possible to examine the effectiveness of each of the two evaluated sub-processes and the product of the efficiency of the subjects in the different sub-processes or whether it is the same as the efficiency of the overall process. According to Chen et al. (2010), the DEA is a method for measuring the effectiveness of DMUs. The DEA has been extended to examine the effectiveness of two-stage processes, where all outputs from the first phase are transitional measures that make up the inputs to the second phase. The resulting two-stage DEA model not only provides an overall efficiency score for the entire process but also provides an efficiency score for each stage. Given the existence of transitional measures, the usual procedure for adjusting inputs or outputs to efficiency points, as in the DEA standard approach, does not necessarily lead to a borderline projection. Also, Mitropoulos (2019) prepared the two-stage DEA model to assess the efficiency of health service delivery. He supposes that within the first stage, we use resources to produce health services as intermediate outcomes. In the second stage, the health services are used to produce final outcomes within the service quality division. These research results emphasize a significance of the DEA model's use also in this analysis in order to achieve the study's aim.

3. Methodology, Variables and Data Collection

We apply a two-stage dynamic DEA model to assess the efficiency of service production division and service quality division. In the first stage, the service production division assesses the utilisation of resources (labour,

physical capital) to produce health services as intermediate outputs. In the second stage, the health services obtained from the service production division are used as inputs to the service quality division to produce final outputs that express the patients´ experiences from hospitals. The conceptual model can be expressed by the following figure (Fig. 1).

In particular, the inputs of the service production division include the number of doctors per hospitalised patient, the number of nurses per hospitalised patient and number of beds per hospitalised patient to satisfy health care for patients. We decide to apply expression per hospitalised patient to eliminate size differences between hospitals. The outputs (intermediate outputs) from this division is expressed by the average length of hospital stay, surgical procedure rate, surgical planning and median waiting time for emergency admission.

The service quality division uses as inputs all the intermediate outputs from the service production division to produce quality and safety health services as expected by patients. The patients´ perceptions of hospitals' quality are assessed by using four satisfaction measures based on the respondents´ ratings of the health care in hospital, the staff access to patients in the hospital, the patient information in hospital, and the hotel services in the analysed hospital. As mentioned by Mitropoulos (2019) the patient safety is an essential issue in health care services. Adverse events, in the process of caregiving, may result from problems in practice, products, procedures or systems.

Source: Prepared by authors

The analysis focuses on assessing the efficiency of the hospitals in Slovakia between 2015 and 2018. Our analysis is done for a sample of 40 hospitals. All variables used in this study are available on an annual basis from the web page www.kdesaliecit.sk prepared by the INEKO. Through this page, the INEKO want to provide objective data and want to draw the public attention to the discussion about the quality and efficiency of medical facilities. If people have more quality information, they can make better decisions and create more effective pressure to improve public services. They want to help the project with patients and their relatives, as well as the facilities themselves. The data come from health insurance companies, Ministry of Health of the Slovak Republic, the Office for Health Care Supervision, the National Centre for Health Information, self-governing regions, Transparency International Slovakia and their analyses. As mentioned by INEKO, some data may be distorted; for example, by the small number of samples and may not correspond to the reality of the device. The complete definition of the health care indicators that are included in the DEA model is available in Table 1.

Table 1. Definition and descriptive statistics of variables included in the DEA model

Indicator	Definition	Min / Max / Average / St.dev
Inputs		
Number of doctors per hospitalised patient	Practicing doctors that provide services for individual patents in hospital; density per 1 hospitalised patient	0.0042 / 0.0356 / 0.0071 / 0.0049
Number of nurses per hospitalised patient	Number of nurses working in hospital; density per 1 hospitalised patient	0.0114 / 0.0542 / 0.0174 / 0.0067
Number of beds per hospitalised patient	Inpatient beds available in hospital; density per 1 hospitalised patient	0.0217 / 0.3124 / 0.0385 / 0.0448
Intermediates		
Average length of hospital stay	Average number of days that patients spend in hospital measured by dividing the total number of days stayed by all inpatients during a year by the number of admissions or discharges	4.2672 / 8.6143 / 6.1100 / 0.9645
Surgical Procedure Rate	The share of operations in the total number of hospitalizations	0.3053 / 0.8280 / 0.6274 / 0.1231
Surgical Planning	It assesses whether only acute cases go to the hospital or whether patients choose it for planned emergency health care themselves.	0.0390 / 0.3211 / 0.1350 / 0.0655
Median waiting time for emergency admission	Median waiting time in minutes	12.15 / 22.40 / 16.77 / 2.59
Outputs		
Health care	Assessment of the patient about the provided health care and improvement of the health condition after discharge from the hospital, on a point scale from 0-5, recalculated to other hospitals	0.6611 / 0.7992 / 0.7251 / 0.0309
Staff access to patients	Assessment of the patient about the time spent by the doctor and the nurses, the availability of consultations with the doctor, on a point scale from 0-5, recalculated to other hospitals	0.6863 / 0.8355 / 0.7660 / 0.0309
Patient information	Assessment of patient information about a diagnosis, clarity of information and patient involvement in decision-making on a point scale of 0-5, recalculated to other hospitals	0.6484 / 0.8094 / 0.7276 / 0.0342
Hotel services	Patient rating on the quality of accommodation, quality of food and quality of cleaning in the hospital on a point scale from 0-5, recalculated to other hospitals	0.5514 / 0.7890 / 0.6481 / 0.0522

As all our inputs and outputs are expressed in the form of ratios, it able us to use model under the assumption of constant returns to scale. As mentioned by Jacobs et al. (2006), this is very common in health care. For example, mortality rates, discharge rates, doctors per head of population, nurses per occupied bed, the proportion of expenditure on clinical supplies from total expenditure, proportion of theatre time for hip replacement operations from total theatre time are commonly used measures of input or output. The essential point to note is that the use of such data automatically implies an assumption of constant returns to scale because the creation of the ratio removes any information about the size of the organisation.

We assume a general two-step process, as shown in Fig. 1, for each of a number of n DMUs. We assume that each DMU_j ($j=1,2...,n$) has m inputs x_{ij} ($i=1,2,...,m$) in the first phase and D intermediate outputs z_{dj} ($d=1,2,...,D$) from this stage. These outputs D then become inputs to the second phase and therefore behave as temporary measures. The outputs from the second phase are y_{rj} ($r=1,2,...,s$). In our case, we assume that in the first phase, the goal will be to determine the minimum number of inputs x_{ij} ($i=1,2,...,m$) needed to produce intermediate outputs z_{dj} ($d=1,2,...,D$) from this stage. For this reason, an input-oriented model will be applied in the first phase. As mentioned by Charnes et al. (1978), the input-oriented model under the constant returns to scale assumption (CCR model) for measuring the relative efficiency of DMU can be expressed as follows:

$$EI_0 = \min \theta_0 \tag{1}$$

$$\text{s.t. } \sum_{j=1}^{n} z_{dj}\lambda_j \geq z_{r0} \qquad d = 1,2,...,D \tag{2}$$

$$\sum_{j=1}^{n} x_{ij}\lambda_j \leq \theta_0 x_{i0} \quad i = 1,2,...,m$$

$$\lambda_j \geq 0 \qquad\qquad j = 1,2,...,n$$

In the second phase, the goal will be to determine what maximum number of outputs y_{rj} ($r=1,2,...,s$) the production unit is able to generate from a given number of inputs (intermediate outputs from the first division) z_{dj} ($d=1,2,...,D$). In this case, an output-oriented model will be applied in the second phase.

$$EO_0 = \max \phi_0 \tag{3}$$

$$\text{s.t. } \sum_{j=1}^{n} y_{rj}\lambda_j \geq \phi_0 y_{rq} \qquad r = 1,2,...,s \tag{4}$$

$$\sum_{j=1}^{n} z_{dj}\lambda_j \leq z_{d0} \qquad d = 1,2,...,D$$

$$\lambda_j \geq 0 \qquad\qquad j = 1,2,...,n$$

In the case under investigation, it is assumed that the value of the intermediated variables is the same, whether they are perceived as inputs or outputs. It is possible to apply two separate DEA analyses into two stages, as reported by Seiford & Zhu (1999). The criticism of such an approach is the internal conflict that arises between the two analyses. For example, it assumes that the first stage is efficient, and the second phase is not. When the second stage improves its performance, the change in inputs (intermediate variable) may cause the first stage to be inefficient. It suggests the need for a DEA approach that ensures coordination between the two stages. As mentioned by Liang et al. (2008), it is, therefore, appropriate to define the efficiency of the whole two-stage process as the geometric average of the efficiency of two phases $E_0 = EI_0$ x EO_0.

As we want to compare efficiency between two years, we can calculate the Malmquist index to measure the productivity changes over time. The Malmquist index can be calculated for both divisions, and also the overall Malmquist index. The Malmquist productivity index evaluates a productivity change of a DMU between two periods as the product of "catch-up" and "frontier shift" terms. The catch-up (recovery or efficiency change) term reflects the degree that a DMU attains for improving its efficiency. In contrast, the frontier shift (innovation or technological change) term demonstrates the difference in the efficient frontier surrounding the DMU between the two periods. We obtain the following formula for the computation of the Malmquist index:

$$Malmquist\ Index = \frac{\delta^2((x_0, y_0)^2)}{\delta^1((x_0, y_0)^1)} \times \left[\frac{\delta^1((x_0, y_0)^1)}{\delta^2((x_0, y_0)^1)} \times \frac{\delta^1((x_0, y_0)^2)}{\delta^2((x_0, y_0)^2)}\right]^{1/2} \tag{5}$$

If the "catch-up" effect value is greater than 1, it interprets the progress in the relative efficiency from period 1 to period 2. The "catch-up" effect value equal to 1 indicates no changes in the relative efficiency, and a value below 1 indicates a regress in relative efficiency. The "frontier-shift" higher than 1 indicates progress in the frontier technology around the evaluated production unit from period 1 to period 2, while "frontier-shift" lower than one indicate regress in the frontier technology. The Malmquist index higher than 1 indicates progress in the total factor productivity change of the evaluated production unit, from period 1 to period 2. The Malmquist index equal to 1 shows a status quo, and the Malmquist index lower than one means deterioration in the total factor productivity.

4. Results and Discussion

The efficiency score for service production division, service quality division and the overall hospital efficiency for the 40 Slovak hospitals are presented in Table 2. The average overall efficiency score for all analysed hospitals was 0.8254 in 2015. Twenty-two hospitals achieved a higher level of overall efficiency compared to the average in 2015; four of them were marked as efficient. On the other hand, eighteen hospitals achieved a lower level of overall efficiency compared to the average in 2015. In 2018 the average overall efficiency was 0.8052, where twenty hospitals achieved a higher level of overall efficiency compared to the average in 2018, five of them were marked as efficient, and fifteen hospitals achieved a lower level of overall efficiency compared to the average in 2018. When we look at the efficiencies of divisions, we can see that the average efficiency of service production division was 0.9160 in 2015 and 0.9102 in 2018. In 2015 twenty-five hospitals achieved a higher level of efficiency compared to the average in the service production division, between them fifteen were marked as efficient, and fifteen hospitals achieved a lower level of efficiency compared to the average in the service production division in 2015. In 2018 twenty-two hospitals achieved a higher level of efficiency compared to the average in the service production division, between them eighteen were marked as efficient, and eighteen hospitals achieved a lower level of efficiency compared to the average in the service production division in 2018. In the case of the service quality division, twenty-one hospitals achieved a higher level of efficiency compared to the average in service quality division, between them twelve were marked as efficient, and nineteen hospitals achieved a lower level of efficiency compared to the average in service quality division in 2015. In 2018 nineteen hospitals achieved a higher level of efficiency compared to the average in service quality division, between them twelve were marked as efficient, and twenty-one hospitals achieved a lower level of efficiency compared to the average in service quality division in 2018.

When we compare the level of average efficiency in service production division and service quality division in 2018, we can see that the level of efficiency in of service production division was higher than in the service quality division. The same tendency can be seen in the case of twenty-two hospitals. The opposite tendency can be seen in the case of thirteen hospitals. In the case of five hospitals, the level of efficiency is the same in both divisions. Comparing the results, we can say that hospitals tend to be more efficient within the service production division. To analyse the relationship between two divisions of hospitals, we have calculated the Pearson´s correlation coefficient, which was -0.1298 in 2015 and -0.1378 in 2018. These results indicate a small negative relationship between service production division and service quality division in both years. The results pointed to the fact that synergy existed between these divisions.

Table 2. Efficiency score in divisions and overall efficiency for selected Slovak hospitals in 2015 and 2018

The next part of the paper analyses changes in the efficiencies using the Malmquist index. The overall Malmquist index (MI) can be decomposed in frontier shift (F.S.) effect and catch-up (C.U.) effect. The frontier shift effect represents an improvement in efficiency due to the innovation, while the catch-up effect represents an improvement in efficiency due to improved operations and management of the hospital and also optimisation in terms of size. While the MI, F.S., and CU above 1 indicate the improvement between periods, the values below 1 indicate worsening in the efficiency. The total improvement, respectively, the deterioration can be calculated as the difference between the index value and the number 1. In percentage form, the difference is multiplied by 100.

Source: Prepared by authors

Table 3 shows the Malmquist index (MI) of each hospital for the overall hospital efficiency, and also for service production division and service quality division. The hospitals are ranked in descending order according to the overall MI. The top-ranking hospital was Faculty Hospital and Polyclinic Skalica (No. 27) with a productivity gain of 76%, while Hospital Partizánske (No. 40) was the lowermost hospital with a productivity loss of 57%. The average productivity growth between two years was 14.57%, and only twelve hospitals exhibited productivity degrees between analysed years. From these hospitals, only four exhibited productivity degrees simultaneously in both divisions. The progress in the overall total factor productivity index was caused by the 1.18% growth in the relative technical efficiency (catch up effect) and positive innovation effect (15.94%) which led to the shift of production possibility frontier. The overall progress was positively influenced by the progress of 12.19% in the case of the service production division and by the progress of 2.63% in service quality division. The progress in the total factor productivity index in case of service production division was caused by the 0.62% growth in the relative technical efficiency and positive innovation effect (12.01%). In the case of service quality division, the progress was caused by the growth in the relative technical efficiency by 0.81% and the positive innovation effect (2.63%). The frontier shift effect representing the impact of innovation was positive in most of the hospitals in both divisions. The catch-up effect was positive in case of both sub-divisions, which represents an improvement in technical efficiency due to improved operations and management of hospitals and optimisation of their optimal size.
Fig. 2. Malmquist index in divisions

Source: Prepared by authors

From the hospitals that exhibited productivity progress, we can see from Fig. 2 that seventeen hospitals achieved progress in both divisions, and only five hospitals achieved degrees in both divisions. In the case of other hospitals, they were able to achieve progress at least in one division. We can see that ten hospitals achieved progress in service production division and degrees in service quality division, while the situation was opposite in the case of eight hospitals. The Pearson correlation coefficient of the divisional Malmquist indexes has also revealed a small negative relationship (-0.1185) between service production division and service quality division.

Conclusion

Human health is a significant dimension in the evaluation of the population's quality of life. Also, it is a biological characteristic, and it has a significant societal value. Priority of each country is to create the best and functioning health care system that would protect, monitor and especially improve population's health status by means of active and efficient health policy (Marešová et al., 2016). Health care market is characterized by many specificities, while the fundamental economic principles are also applied here. These principles create a space for potential conflicts, as well. It is connected to efforts that satisfy health care demand. However, the budget is

limited. Demographic prognoses and informatization growth demand for health care, while covered by limited financial resources. Sustainability of health care systems is a priority in a short-term and also long-term horizon. The creators of health policy and other stakeholders need to face increasing pressures which result in the implementation of more systematic and effective ways of health care systems' measurement and evaluation in order to improve public health as well as health care, responsibility, management and effective use of resources in health care. Measuring the effectiveness of health systems is a cardinal issue in most of the countries.

The Slovak health care system provides a wide space for inefficiency decrease. The study's subject was all of the facts mentioned above. Its main aim is to examine relationships between the production of services and the quality of services in the process of providing health care at the level of hospitals in Slovakia and subsequently, evaluate the rate of differences between them. The Malmquist index evaluated the total efficiency of each researched hospital. Similarly, efficiency in its two researched divisions, service production division and service quality division, used the same index.

As a consequence of this fact, it is possible to create a scale of hospitals according to their hospital efficiency. The analyses results show significant differences in efficiency among individual hospitals. It will influence a different availability of health care among regions, as well as on a different rate of patients' satisfaction. Also, this rate will influence differences in health care demand within regions, and subsequently, it will influence a deepening of the regional disparities in health. The study's results provide a valuable platform for the creation of national and regional strategic health plans, whose aim is to eliminate disparities in health in the individual regions. Thus, these plans may create mechanisms for providing a sustainable health care system in Slovakia. The question of public health systems' sustainability enormously increases even in the context of the global threats of epidemics, such as COVID-19 pandemic.

Abstract. The Coronavirus SARS-CoV-2 (COVID-19) pandemic caused a global substantial effect whilst affecting local healthcare systems and productive sectors among many others. It was a "wake up call" for the economy (investors), policymakers (governments) and the entire society. Progressively, it became widely obvious there is no "going back to normal" and a new normal will gradually be in place. Many questions were raised in this uncertainty situation including how this new normal will affect productive sectors? How can countries leverage the new realities forced on them by COVID-19 to shape better future plans or to achieve their pre-identified goals efficiently? In the middle of this global chaos, are their opportunities for developing economies? This paper tries to answer these questions with specific emphasis on Egypt using foresighting tools while highlighting the best-case and worst-case scenarios for Egypt in the post-COVID-19 world.

Keywords: COVID-19; impact, economy; policymakers; society; scenarious, Egypt

---

1. Introduction

By beginning of December 2019, several cases of pneumonia of unknown etiology were reported in Wuhan, Hubei province, China (Huang C et al., 2020). This was later officially named coronavirus disease 2019 (COVID-19) by the World Health Organization (WHO). Very quickly, COVID-19 had been classified as a global pandemic. As of May 21, 2020, COVID-19 pandemic has affected about 5 million people and claimed over 328,471deaths globally (Johns Hopkins, 2020).

The rapid spread of COVID-19 has basically halted the global economy. It has inflicted high, and rising, human costs worldwide given that that the necessary protection measures severely impacted economic activity. This had severe impact on the livelihoods of many millions of people especially in economies with large percentages of daily wage earners. As a result of the pandemic, the global economy is projected to contract sharply by 3% in 2020. (World Economic Outlook, 2020). While scientists are feverishly seeking vaccines and cures, policymakers are desperately working to implement market, monetary and financial measures targeting the market to support locally affected families and companies. The health, economic, social, and political impact of this pandemic have changed the world as we know it and will push everyone to re-evaluate their priorities and build new alliances.

COVID-19 has already had a severe impact on the health system, scientific research, food energy environment, financial, tourism, sports as well religious practices. Impact has been by and large negative but, in every field, there appears to be new opportunities opening from this negative starting point for the post-COVID world.

In education, most countries closed schools, colleges, and universities to reduce contact and save lives. Teaching, like many businesses, moved online, on an untested and unprecedented scale. Many student assessments also moved online while others were forced into using project work for assessment, with a lot of trial and error and uncertainty for everyone (Simon & Hans, 2020). However, on the positive side, it has been a great transformation leading to popularization of the use of technology in education that can lead to a complete revaluation of the modes of learning and assessment.

As countries went into lockdown, most industrial activities shut down globally including commercial aerospace, travel, apparel, luxury, automotive industries, and insurance. The crisis has also amplified existing challenges by millions of workers all over the world who are facing the prospect of losing their jobs (Abhijit et al,2020). However, it has also catapulted the idea of work for home and will lead to a transformation of the work culture.

Transport is one of the most hard-hit sectors due to lockdown. Road and air transport came to a halt as people were not allowed or hesitated to travel. According to official reports, air travel dropped by 96% due to COVID-19: the lowest in 75 years (CNN, 2020). COVID-19 will require a complete transformation of the airline business. It will surely force people to reconsider their mode of transportation and result in a total transformation of airline and tourism industry. Egypt, like the rest of the world, closed airports and restricted travel excluding only the return of Egyptians from abroad.

While COVID-19 has had a severe negative impact on human lives and the global economy, it has had an unexpected positive impact on the environment and climate change and sustainability. Air pollution levels have dropped significantly due to limited social and economic activities (Dutheil et al., 2020). NASA Satellite images of the northeastern part of United States, showed that CO_2 emission concentration in March 2020 dropped by up to 30% due to lockdown, compared to March 2015 to 2019 (NASA, 2020). This unexpected positive change alongside the realization of the fragility of our civilization has restored the belief that indeed, something can and

must be done about global warming replacing the sense of inevitability that was prevailing before COVID-19. There is no question that the COVID-19 experience will energize the drive for the protection of the environment in the post COVID world.

In the recent years, the world saw a rise in nationalism and isolationist policies pushing for individualism in dealing with global challenges like climate change for example. COVID-19 was a grim reminder that the best of health care systems and strongest economies are not a protection from pandemics and what hit one country, quickly resonated around the world. Most nations quickly learned that fighting the pandemic requires collaboration amongst medical experts to find cure and vaccine as fast as possible. Coronavirus CAN represent an opportunity to review how humanity can work together beyond national boundaries to face common challenges. (Mohamed and Dunya, 2020).

Based on all the above we argue that while COVID's massive disruption of the world order as we know it has been devastating, it presents the possibility of a fresh starting point for the world. There is no "going back to normal". The world will establish "a new normal". Countries who attempt to simply return to business as usual face serious negative consequences as the world is no longer what it was. Those who will emerge successfully from the COVID-19 devastation are the ones who recognize that the governing rules, constraints, and opportunities have completely changed, and everything must be reassessed. This necessitates new foresighting exercise to envision the plausible scenarios for the future depending on how the world reacts to the new drivers shaping the post-COVID-19. The question is what will that new normal be?

Since the start of foresighting with Shell Corporation in the energy sector, its use has spread widely. Governments and corporations have conducted foresight studies to better plan technology-related investments (Reger, 2001), to prepare for potential bioterrorism attacks, and to envision the impact of global warming.

Foresight goes hand in hand with future studies and is closely associated with scenario-building (IPTS, http://forlearn.jrc.ec.europa.eu/index.htm). Recently, we saw more reliance on future studies to prepare for the future (Rezk, et al, 2019). The purpose of a foresight project is as much for helping today's decision-making as it is for creating awareness about tomorrow's challenges and opportunities through building detailed scenarios of alternative plausible futures along with what must be in place to make them happen.

Scenario planning is an increasingly applied strategic process in a variety of contexts (Amer, Daim, & Jetter, 2013; Chermack, 2017; Varum & Melo, 2010). Because of the applied nature of scenario planning, it has grown into a standard practice for most organizations and many countries (Amer, Daim, & Jetter, 2013; Varum & Melo, 2010). Recently, many scenarios were developed for the world post COVID-19 (Mohamed and Dunya, 2020). Most have focused on the "health aspects" with the driving factors being the discovery of vaccines. Many others developed scenarios based on the economy rebounding very slowly, fast or intermittently as a result of the vaccine availability. The recovery effort would require several strategies. Looking at the pre-COVID-19 environment, it is clear that momentum has already increased around the need for a framework reset; several leading companies have stepped up and invested in this revolutionary direction, while innovative government agencies have put forward significant legislative initiatives to allow the transition. (Jocelyn Blériot, 2020).

This paper presents a foresighting exercise to provide alternatives for the future of Egypt in this new post-COVID-19 global context through best case and worst case scenarios intended to help politicians capture the emerging post COVID-19 opportunities and shape a future that was difficult to envision before COVID-19.

We assume that a vaccine is available, and the health aspects of the crisis are under control. The paper focuses on a select set of areas to highlight the opportunities to build a better post corona world and the huge losses if these opportunities are not captured.

2. Methodology

In this paper, we follow the standard approach of writing two archetypes scenarios (Hunt et al., 2012): the best case scenario and worst case scenario. We start with defining the key drivers that affect the future of Egypt through the perspective of specific selected sectors. The scenarios are built by interlinked interaction among these drivers. Both scenarios start from assumptions of availability of vaccines and reasonable economic recovery.

2.1. Defining Key Drivers of Uncertainty

We start with identifying the drivers shaping the future to construct the best and worst scenarios. In this context, the drivers are classified into internal and external drivers that could influence the future of selected sectors (Table 1). The listed drivers incorporate national and international trends for the world after COVID-19.

Table 1. Internal and External drivers for Egypt in the post COVID-19 world

Internal drivers	External drivers
National political leadership action	Changes in world leadership
Centralization of services and state control	Global collaboration on global challenges
State surveillance	Geopolitics
Culture and social attitudes	Globalism vs nationalism
Social, economic and development priorities	Global priorities
Social cohesion	Freedom of movement
Focus on public health and healthcare	Interest in tourism
Technological innovation and R&D investment	Investments, external funds,
Information and communication infrastructure	Diversification of sources/supply chains
Scale of technology adoption	Technological innovation
Digitalization of services	Data protection/sharing globally
Data protection	Workforce culture, automation
Workforce culture	Efficiency vs resilience
Institutional agility to cope with the dynamic changes and uncertainty	Economic recovery
	Vaccine availability
Economic recovery	
Vaccine availability	

2.2 Building of Archetypes Scenarios

Most scenarios already available on the international scene focus on alternative plausible futures for the world depending on early availability of vaccines versus late availability, on virus mutation and on no availability of vaccines or alternative scenarios based on economic assumptions and focused on economic recovery (Deloitte, 2020).

In this paper, the best case scenario (The rainbow after the rain) describes the future if everything lined up perfectly while the worst case scenarios (When the sun never rose again) describes the future if no effort was made to leverage the opportunities created by COVID-19 and Egypt continues business as usual where it left off before Corona as the world moves to the new normal Drivers are incorporated in each scenario.

2. Results and discussion

In this paper, we assume that a vaccine will be available on a wide scale by the end of the year and that the economy will be recovering at a reasonable rate. Our focus is on capturing the opportunities in this post-COVID-19 world as a direct consequence of the transformations that were never before imaginable while focusing on Egypt as a case study. Capturing these opportunities might inform future strategies and policymaking processes to design actions and interventions that better suit the new realities. Ignoring these opportunities and returning to "normal" in a world that is no longer "normal" might not just miss opportunities but rather result in significant deterioration and negative impact on existing plans. The scenarios focus on a select number of fields as examples to drive the idea of capturing post COVID-19 opportunities. Next level would be a more detailed analysis by experts in each field.

3.1. Best Case Scenario "The rainbow after the rain"

When Covid-19 hit, it brought the world to almost a standstill. Hospitals were overwhelmed, and people were dying. Those who were not sick were terrified of becoming infected. Borders around the world were closed. Air traffic came near to a complete shutdown. Universities, schools and factories shut down across the globe. Oil and gas consumption and their price crashed. Stores, gyms, restaurants and businesses closed. People were laid off, and stock markets plunged.

However, at the same time, wars slowed down. Pollution decreased in clearly visible ways. Nature started healing itself. People started getting together to help one another. Poorer countries were helping rich countries. People discovered online technologies could achieve that much in personal and professional communication as well as education. Families started spending more time physically together. A new world was born with a new order and new rules for a new normal. The world recognized that its complete dependence on China for all its manufactured products was a fundamental mistake that endangered lives of millions of people around the world. This was an essential reminder of the necessity of diversifying sources of essential commodities. Governments were reminded of the vital importance of investing in health and a new reality of "working from home" was suddenly the norm.

The Egyptian government was quick to understand that there is no going back to the world before Covid-19. While ministries focused on dealing with the pandemic to stop its spread amongst Egyptians, the government coordinated several thinktanks to plan for the new realities post -Covid-19 based on the lessons learned across nations. Work started on best positioning of Egypt for the world post-Corona even before the pandemic was under control (IDSC, 2020).

3.1.1. Health

COVID-19 shock resulted in a complete re-evaluation of priorities. Public health is now a top priority from both a medical and an economic perspective when it was realized that stopping the spread of a disease is a much more effective strategy than dealing with the resulting morbidity. The economic value of public health is now a critical parameter in government decisions. Massive campaigns have been initiated to instil the culture of prevention of disease, healthy eating and living. People became much more receptive to such messaging when they realized that the majority COVID-19 deaths occurred in people with pre-existing chronic diseases. Smoking, high consumption of sugar and saturated fats became socially frowned upon, and consumption dropped significantly. Walking and cycling are now the more practical choices, especially that new cities had better planning for bikers and walkers. Sidewalks are clear of coffee shops ad other obstacles and Egyptians have since adopted a lifestyle that includes exercise as a preventative health measure. The government reassessed its food rations to the

vulnerable groups to ensure their nutritious value and additional taxes were imposed on "junk food" to further discourage their consumption. Egyptians instinctively understood the risk of the multiplying effect of chronic diseases, like diabetes and hypertension, on their exposure to death and are now much more health conscious.
Covid-19 taught the world a huge lesson about the importance of prevention of infection in hospitals and protection of hospital staff and other patients. Following the pandemic, the Egyptian government continued to impose a strict culture of infection control across its hospitals with the full support of healthcare workers who understood clearly that this is for their safety not just that of the patients. Infection control governing healthcare professionals working across hospitals are strictly now in place to stop the infection transmission.

The threat caused by pre-existing health conditions and the importance of knowing what they are to determine the COVID-19 treatment resulted in a major push for personalized medicine. As part of the health insurance system that was being introduced in stages, Egypt now has a personal electronic file for every public insurance patient accessible from every public health provider. This ensures a far much better health care system. It is also driving a national database for all patients.

During the extended period of partial lockdown, many physicians closed their clinics severely limiting access to healthcare while patients hesitated a lot before seeking healthcare except for real emergencies. Meanwhile, other doctors came together and volunteered to offer free general online advice. This was extremely welcomed by many and was the beginning of the transformation. Now, many physicians have online group presence through which they provide basic simple medical advice to patients at much reduced prices but allowing quick access to professionals for the simple cases that may not need physical presence. This was the catalyst that opened the door to todays' world of telemedicine serving remote areas as well as basic needs.
COVID-19 also raised the issue of cleanliness and disinfection across the country as the armed forces scrambled to disinfect buildings and streets. Sanitation and disinfection of all public places is now a standard required procedure post-COVID-19.

Waste collectors are now issued gloves for their safety as well as tools to allow them to clean the sites without exposing them to disease effectively. The whole idea of the virus surviving on surfaces required a severe re-evaluation of the safety of the food supply in Egypt, mainly food sold on the street. On a related issue, what happened during the peak of COVID-19 with people hording any medicine or vitamin rumoured to be useful in its treatment has driven the Egyptian Ministry of Health to reconsider public access to medication without a doctor's prescription. While the current system still does allow some access without a prescription to simple medications in recognition of the reality in Egypt, the list of restricted medications has been greatly expanded to break the culture of unnecessary consumption or hording of medicine.

Most importantly, today in Egypt National Security now includes Health Security at the same level of importance as food security and water security. This includes having a national stockpile of medicine and critical hospital equipment to cover the nation for a set number of months just as there is a nationwide inventory of food and water. This also includes a stockpile of raw materials needed for local manufacturing of strategic health security products.

3.1.2. Industry

On the industry side, the world reassessed its past focus on efficiency. Resilience, self sufficiency or at least diversification of sources in the supply chain became the new priority. It was clear that as the world scrambles to diversify its sources for products and to break its now-dangerous dependence on China, opportunities will open for countries centrally located like Egypt to step in and be an important node in the newly established network of manufacturing hubs. Egypt's location, central to both Europe and Africa gave it a natural advantage. This

opportunity was made more likely to turn into reality as Chinese businesspeople were keen to ensure they retain their market share and as such, were quite interested in opening up factories for their products outside of China. This started with announcements for SAMSUNG in late May about expanding their facilities and product line being manufactured in Egypt. Many other industry giants quickly followed suit. The government did exceptional effort to facilitate their entry into Egypt resulting in a huge boost to Egyptian industry. Made in Egypt is now a trusted brand across Middle East, Africa, and Europe (Daily news Egypt, 2020).

COVID-19, as well as the government action to attract Chinese and other manufacturers to Egypt, did not just push the industry forward, but it had a transformative impact on scientific research and innovation. While the Covid-19 crisis pushed local innovators to produce face protectors, respirators, and applications to help in tracing contacts, one factor was critical in driving applied research in Egypt. The government required all factories opening up in Egypt to invest a small percentage of their profit on research and development of their products in Egypt through the collaboration of the Egyptian branch of their business with their other branches and with Egyptian researchers. This had a transformative impact driving applied research in Egypt and leading other industries to do the same. As a result, Egypt is now a global competitor in many products not just manufactured in Egypt but also designed in Egypt.

3.1.3 Education

When it came to Education, the abrupt closure of schools and universities thrust everyone into the world of online learning. In Egypt, private schools moved into it instantaneously which was not surprising, but the big surprise was that the public-school system followed very soon after. Given that the ministry was pushing hard in that direction against significant opposition of the change, the Covid-19 imposed closure was a massive boost to the Ministry's efforts. It was an incredible moment of transformation that was seized to drive a complete overhaul of pre-university education at a pace never dreamt of. COVID also forced the acceptance of projects as an evaluation tool in public schools. This was a transformative cultural change that was maintained later as a critical component of the evaluation leading to the current education system. Egypt now has a system that expects and supports independent learning of its students and assesses them on their ability to learn as opposed what was the norm of assessing them on the basis of what they memorized. The transformation that people assumed would take 12 years to complete starting from Grade 1 is now in place after barely two years. COVID-19 eliminated the opposition and opened the way for what is now looked at as a historic transformation.

University education was settled in traditional learning modes and was not as ready to integrate online delivery as pre-university education was. Professors had to arrange for their online delivery in their own independent ways and to choose means of assessment to end the first term in 2020 (except for final years). However, the Supreme Council of Universities acted fast during the summer of 2020 to build on this dramatic change that happened in both university and pe-university education. A high-level committee was put together to explore ways of improving the quality of learning using this technological experience developed so quickly during the pandemic as well as accepted means of assessing learning. When classes returned in Fall 2020, there was no going back, and Egyptian universities had developed a blended learning model where technology is used extensively to invite global experts in live sessions, students learned independently and the lecture time is used for more in-depth discussions, case studies or working out examples. In a word, the classroom is now "inverted" and the learning is "blended".   Course evaluation systematically included independent research projects as well as video presentations. In short, the pandemic resulted in breaking all the barriers that slowed down the inevitable transformation in university education and opened up massive opportunities for independent, high-quality blended learning where the teachers became mentors guiding the learning process and students were expected to "learn to learn" by researching the material themselves.

3.1.4. Workplace Culture

Amongst the traditions destroyed by COVID-19, workplace culture was right at the top. Hundreds of millions around the world were forced to work from home conducting the most massive experiment to assess the good and the bad of such experience. The government in Egypt quickly imposed a stay at home or work from home ruling for its employees except those designated as essential workers. The value of existing online government services was obvious. Banks advertised new ways to complete transactions online. Phone companies provided incentives for using online services. Just as the fear of technology in education was broken, it was also broken in work cultures in private companies as well as the government.

Following COVID-19 many government departments realized the value of allowing employees to work from home. Work from home is now accepted with the added transformative benefit that employees are now assessed based on productivity and not on attendance.

The reduction in the capacity of government workers during the quarantine time highlighted the excess employment in government services. Many of these services continued with those designated as "essential". This caused a significant re-evaluation of the number of employees needed in each department. Attractive severance packages were offered to people to retire/resign and many took them up. In some areas with excess capacity and limited work options, employees were given choices of reduced work week with proportional cutback in salary. This option was welcomed by many lower middle-class women eager to spend time at home.

At the same time, the government opened the door for redistribution of workers where they may be required, with necessary retraining. The government also announced a competition for new initiatives. Those proposing new initiatives were allowed to take a leave from their positions to lead the realization of their initiatives and to recruit others from within the government labour force. This resulted in a complete "reimagination" of government and utilization of its extra capacity to provide expanded more friendly services with minimal overhead.

Currently, the government has moved much more aggressively to drive the painfully slowly moving e-government as citizens were significantly more willing to adapt now that they are more comfortable with technology and more fearful of crowded places. This change has been instrumental not only in modernizing the workforce and services but in curtailing corruption across government and streamlining its services.

The private sector was even more innovative in its approach embracing work from home were possible and establishing the blended week principle where employees worked from home 3 days a week and had to come in only two days a week.

A side benefit this dramatic change in workplace culture and in university/school education had was a really positive unexpected impact on the environment through reducing transportation to and from work while it significantly improved family ties as people now have grown to expect/demand family time.

3.1.5. Informal sector

A significant component of daily wage earners was no longer able to get any employment opportunity as the quarantine was established. The government was swift to recognize the need to provide emergency financial support for them. This highlighted the absence of economic sustainability for a large segment of Egyptian society. As a result, the government put in place a "Pensions for all" initiative to allow daily workers to contribute to a small pension fund with generous interest rates provided the funds are not withdrawn before the age of 60. Participation in this fund also made these wage earners eligible for emergency government assistance in times of need. This initiative was welcomed by over a million people. It started a shift amongst Egyptians to a culture of

planning for the future rather than living day-to-day and then needing complete government assistance in old age. Those who chose to participate in pension planning were included in a database that was used by companies to search for skilled workers. Workers were rated by their employers which improved their opportunities of being hired by other companies in permanent positions.

On the social level, the system put in place during quarantine led to the respect of specific working hours for stores and coffee shops as well as significant improvements in "social order" in using lineups for example at busy stores. The government succeeded in maintaining these limits on store hours after the quarantine was lifted, resulting in a significant reduction in electricity consumption and more importantly increased family time.

3.1.6. Environment

COVID-19 brought the world to a crawl. It was almost like nature was fed up with the excessive pollution in the world and was tired of global warming and decided to force a stop. This temporary stop in industrial activities and transportation showed clear evidence of nature being able to heal itself much faster than was believed possible just prior to COVOD-19. The ozone layer fixed itself, and the hole of the arctic has closed! By the end of April, the quality of air in Egypt improved by 40%. (CAMS, 2020)

This resulted in a renewed resolve globally to protect the environment as we push for sustainable development. Here in Egypt, driven by an increased awareness of the social and economic value of public health, this caused a significant overhaul of the system of enforcement of environmental controls in all sectors. It also strengthened the government's resolve to decrease Egypt's dependence on fossil fuels and increase the percentage of renewable energy produced and waste. Laws were passed to ensure new cities were designed to require solar energy production and minimize energy consumption and to rely more on public transportation. Pre-university education ensured children understood the importance of caring for the environment, and university education challenged students to come up with environmental innovations that can be manufactured locally. Special funding was made available for changes that can improve compliance with environmental regulations.

3.2. Worst Case Scenario "When the sun never rose again''

When COVID-19 hit, it brought the world to almost a standstill. Hospitals were overwhelmed. People were dying. Those who were not sick were terrified of becoming infected. Borders around the world were closed. Air traffic came near to a complete shutdown. Universities, schools, and factories shut down across the globe. Oil and gas consumption and their price crashed. Stores, gyms, restaurants, and businesses closed. People were laid off, and stock markets plunged. Divorce rates increased as families were forced to spend more time together than they ever did and there was a marked increase in domestic abuse. Unemployment skyrocketed, businesses declared bankruptcies and the world was turned upside down. Suddenly, the western countries regarded as invincible were extremely vulnerable and unable to protect the lives of their people or protect their ability to work and earn a living. Third world countries, whose health acre systems were fragile to start with, were left to fend for themselves against the virus and the culture of the people that made its spread much more likely and its treatment a lot less likely to be successful. The geopolitical scene changed dramatically and globalization, which was once an opportunity, was now seen as a threat to both global economy and global health.

A new world was born with a new order and new rules for a new normal. And Egypt was not ready for the change.

The Egyptian government was overwhelmed by the immediate health and economic devastating impact of COVID-19. As it worked on minimizing loss of life and restoring the economy back on the positive track it was following, the terrorism threat remained a top priority requiring significant attention and investment. At the same

time, retaining the state of social rest in the face of internal forces itching for reasons to recreate uprisings was always the overriding constraint. This limited the government willingness to take drastic actions needed for long term growth in this new world and forced a strategy of "avoidance" of change that may create unrest. Once the spread of the virus was somewhat under control, the government was completely focused on going back to the where things were before Covid-19, resuming its original plans with a lot less resources and avoiding any changes that may upset citizens already under significant economic hardship.

3.2.1. Health

The government of Egypt took on the treatment of all COVID-19 case at the government expense. This was a massive unexpected cost at a difficult time when the government trying to rebuild the country's infrastructure, provide social security to its most marginalized, create job opportunities, ensure security, reimagine education and other ambitious projects. It was also coupled with a complete stop in tourism revenue and massive drop in remittances from Egyptians abroad. This huge health cost drain on the already battered budget ended up adversely affecting future investment in the health sector that was had already used up funds originally targeted to other areas.

This was complicated by the fact that Egypt fared much better than ever expected regarding number of deaths compared to western countries of similar size. No scientific explanation existed or was sought as to why Egypt and Africa in general was not as devastated as was initially assumed. Instead, many "theories" have existed and were tacitly accepted about certain vaccinations, the weather, pollution, diet, genes and others. At the end, it was the general belief of most Egyptians that "God takes care of Egypt and will always do". In a very strange way, surviving a huge scale COVID-19 devastation resulted in a belief in "natural immunity" and more disregard for public health, sanitation, food safety or healthy lifestyles on both the individual and government sides. After initially arguing "we must work hard to not repeat the Italian scenario", the prevailing belief was "The Italian scenario can never be repeated here" and people's relaxed attitude towards public health, infection control and other issues became even more relaxed. Given that the government made no effort to understand the reasons behind the relatively limited devastation in Egypt, they made little effort to correct this dangerous public perception.

As the harsh economic environment post COVID-19 reality settled in, the government, keen on avoiding social unrest, was quick to increase the food rations for the marginalized. However, it was unwilling to risk upsetting people by using the opportunity to introduce healthier food options and continued the tradition of including more of "sugar and oil" ensuring the continued unhealthy diet for most needy Egyptians and as such the continued spread of chronic diseases like Diabetes. Such diseases are now so common that they have become accepted as unavoidable part of life. Patients of such diseases continue to overload the system making it impossible to improve the quality of heath care especially given the reduced post-COVID investment in health. Egypt was solidly in a closed cycle of poor public health and nutrition leading to more sick people draining the system more leaving it unable to address long term issues of public health, nutrition or healthy lifestyles.

This deterioration of health care services was exasperated by doctors raising their fees in an effort to make up for lost revenue in the time of Corona and as usual, such increased fees were never later reduced leaving many patients unable to access basic health care. The online medical services that sprouted during COVID-19 continued in a completely unregulated form resulting in significant medical malpractice preying on people unable to access doctors because of their very high fees.

While at one point before COVID, Egypt had started to move slowly towards transformation of its health care system, COVID totally derailed the plans and Egypt is now in much worse shape that it was before.

3.2.2. Industry

Prior to COVID-19, the Egyptian government had long term plans for reviving Egyptian industry. As soon as there was some control on the virus, the government went back to continue where it left off focusing on the exact same areas in its efforts to revive local industry. However, the world had changed. The Egyptian economy like all economies was hit hard and the government had limited resources to invest. It was also much harder to attract foreign investment as the markets had changed dramatically with the world's focus on diversifying from China's hold on manufacturing and the original plans of Egypt did not fit the investors new goals. While investors were keen on investing in areas that help Europe and Africa reduce their dependency on China, Egypt continues pushing its predetermined areas for investment. Investors chose to go where they can address the new needs of the market leaving Egypt empty handed.

While efforts to push local production continue, these are simple incremental efforts that seem ineffective as the world has rearranged its manufacturing priorities. Jordan, Morocco and Alegria captured the opportunities for industrial growth in ways they never could have captured had they been competing with Egypt.

Factories can barely stay operational and need significant government support. They are focused on local market which is not sufficient to allow for growth and to create enough jobs. Unemployment is at unprecedented high levels and foreign currency is at unprecedented low levels resulting in difficulties in importing raw material and consequently further complicating life for industry.

Given that industry is suffering greatly, there is no interest in supporting scientific research and not even product development as businesses go back to survival mode as in post 2011. Egypt's competitiveness continues to deteriorate and as it becomes harder to attract investors or market products, industry's interest in innovation or even development continues to dwindle as businesses are preoccupied with daily challenges. The field of innovation and entrepreneurship which was on a high growth rate track is now practically non-existent.

3.2.3. Education

It seemed the pre-university education sector was the most prepared to handle the COVID-19 crisis of school closing given that the ministry was pushing hard for technology-assisted learning prior to Corona. While indeed, the whole system switched to using online education tools, this transformation did not last long, and the ministry was not able to capture the spirit of the change imposed on the system. Teachers refused to accept change to blended learning and worked to disrupt the system. Parents tired of home schooling were unable to appreciate the importance of independent learning or value of projects in place of exams. They were convinced they had more control on results of exams based on memorization. Private tutors eager to re-establish their business and convinced they make higher profit through in person classes managed to re-establish their hold on the learning market. Even private schools were eager to return to normal" to justify their higher fees. While they all acted independently, they were all united in opposition. The government was too concerned about the social unrest that might erupt by antagonizing such broad sectors of society and they caved in. As quickly as everyone turned to online education, everyone turned back to business as usual with the ministry succeeding in only incrementally moving for expanded use of technology aids to learning and reform of learning objectives. This resulted in the waste of significant funds invested in technology as teachers and parents kept pressuring for old fashioned learning resulting in Egypt continuing to fail its young people by not preparing them for the new world were independent learning using technology had become the norm. Egyptian graduates are now further back on world ranking than they ever were making university education even harder and reducing Egyptian graduates' chances of competing regionally and internationally.

University education was already settled in traditional learning modes and was not as ready to integrate online delivery as pre-university education was. While professors did manage to find online ways to finish the year and based their assessment on group projects, everyone was very eager to go back to their comfort zone as the new academic year started. The Supreme Council of Universities was relieved that the crisis was over and went back "to normal" seeing no reason to change. Students were very anxious about evaluation systems requiring them to learn independently and while they complained about spoon feeding, they quickly realized they can study easier and guarantee grades better in such a system.

Today, as the world moved on to adopt independent learning on a previously unimaginable scale, Egyptian universities continue in "teaching" rather than creating an environment for "independent learning". Students continue to "study for the exam" to maximize grades with no interest in actual learning. The learning environment continues to be based on memorization and as such does not sustain any innovation or creativity. The world that technology opens for learning remains foreign to most Egyptian graduates impacting not only their university learning but their ability to continue learning after graduation.

This has had a very negative impact of the Egyptian workforce as that resistance to technology in education spilled into the workplace. It also had a severe impact of the competitiveness of the Egyptian graduate abroad. Egypt is no longer a key source of advanced skills regionally. This inability to compete regionally left all graduates looking for jobs at home and not finding much. Unemployment has skyrocketed and entrepreneurship disappeared. With a government keen on avoiding social unrest, this resulted in increased support for poverty as opposed to long term initiatives to create employment to break the poverty cycle.

3.2.4. Workplace Culture

COVID-19 forced a sudden and almost complete stay at home/work from home rule on government and private businesses.   There was considerable hope for a complete overhaul of the government workforce post COVID-19 to determine who is deemed essential and who can continue to work from home reducing traffic and crowding and allowing more efficiency. However, to allow people to work from home, there had to be a mechanism that measures performance based on productivity as opposed to simply physical attendance. There was a brief attempt to put such a system in place but given the massive opposition developed to it, it was dropped. People who were used to attendance being fundamentally the main work requirement were too concerned about productivity assessment and how it will be applied. They realized it will require more work from them and may indicate that they are dispensable and in principle did not trust its fairness. The opposition was very strong and the work required for a complete new assessment system was significant enough that the government ended up dropping the proposal, again to avoid potential unrest caused by 6 million disgruntled government employees and their families. Work culture went "back to normal".

However, as a consequence of the success to block renewal of the workplace, those opposing change were energized to further slow down the already slow progress of e-government. All hopes for use of e-government to stop corruption by separating the user from the employee faded. As the world moved on to a complete overhaul of services and went online facilitating access and making corruption basically impossible; Egypt ended up with a strengthened traditional workforce and more deeply rooted every day corruption. This caused significant frustration to Egyptian citizens fuelling their sense of helplessness and anger at the government seeding discontent and at the same time requiring other government concessions to avoid unrest.

On the private sector side, work-from-home culture continued for a while on a hesitant basis. While the companies tried to make it the norm wherever possible, the overall social culture was very resistant to change and work from home continues to be the exception.

3.2.5. Informal sector

After the hit taken by the informal sector, the focus was on returning these daily wage earners to earning their living. The fact that the government and the civil society and generous individuals stepped in to help removed the urgency of long-term planning. The government focused on creating temporary jobs for this class of workers and the focus of workers was on restoring their ability to earn enough daily. This kept a large segment of society living in a very vulnerable state and continued the culture of dependence on the government as the saviour. Indeed, the quick intervention of the government in case of COVID-19 raised the expectations for future interventions. The assumption now is that in times of economic difficulty, the government must step in and if it did not, social unrest will result. This added a sizeable drain on the economy specifically given that there is no way of verifying whose income was really affected and whose income was not. The size of the informal sector is so huge that abuse of government support for those in need is quite easy and again, hesitation to block abusers in fear of social unrest resulted in significant waste of government funds. The newly developed sense of dependence of the informal sector on government coupled with energized forces opposing change in government, education and other areas lead to a paralyzed government that chose to go back to the concept of general subsidy for everyone to avoid social unrest. That was a massive blow to the structural economic changes the government had been working on successfully pre-COVID-19.

On the social level, following the hours of operation limitations imposed during the quarantine; there was a pent-up interest in socializing for both operators of cafes and restaurants and their customers resulting in total chaos in times of operations as well as illegal use of street space for offering services. Streets of Egypt and the big cities became more like slum cities with cafes and street vendors popping up on every street and street corner and taking over sidewalks. The police were totally drained in policing quarantine and as such after quarantine was lifted, they turned a blind eye to violations allowing exponential growth. This drove pedestrians to simply move to the streets competing with cars, slowing down traffic and causing more accidents. Despite the significant investments to restore Egypt's grandeur and impose rules and structure on the streets pre-COVID-19, Egypt's major cities are now more like slums and the government gave up on applying its own regulations.

3.2.6. Environment

When the COVID-19 pandemic hit, it was expected that it would ravage through Africa specifically given the density of population, the widespread existence of chronic conditions and the poor state of healthcare compared to western countries. However, it soon became apparent that reality was the exact opposite. While of course there was a significant impact economically as well as in terms of deaths and load on healthcare systems, Africa in general and Egypt survived with relatively lower number of deaths. As scientists worked on understanding what happened, all kinds of social media theories spread. In particular, one theory that gained credibility was a combination of religious belief that God was looking out for Egyptians in particular and that the pollution in the air is what weakened the virus and slowed down its spread. While this was never an official position, it led to a strengthened culture of inaction on environment and tacit belief that pollution is not so bad after all.

As the world moved aggressively towards retaining and driving the improvement in environment brought about by the COVID shutdown, Egypt moved in the opposite direction opening its doors to "dirty industry" as a desperate attempt to create jobs. The quality of air in Egypt is now recognized internationally as one of the worst. This has had an added devastating effect on tourism and tourists who were now more health conscious avoided travelling to Egypt as well as on the health of Egyptians overwhelming a sector that is barely keeping up.

4. Recommendations:

A. Political leadership accept the principle of there being no "normal" to go back to. A new world order is in place now.
B. Fast and quick action based on freedom from past assumptions about what can work and what cannot work and preparedness to control forces trying to go back to business as usual.
C. Government, businesses, NGOs and citizens identify and capture the new opportunities created by the world's determination to ensure resilience rather than efficiency.
D. Government, businesses, NGOs and citizens identify and capture the new opportunities created after established cultural norms have been decimated during quarantine.

5. Conclusions

COVID-19 has certainly been a wake-up moment for the world. Some countries understood the "no going back to normal" reality while others were exhausted fighting COVID-19 that they barely had enough energy to go back to the old normal; and they were doomed. In this paper, we present best- and worst-case scenarios for the case of Egypt hoping these scenarios would alert decision makers to the incredible opportunities Egypt has in a post COVID-19 world and the disaster that will follow if these opportunities are missed.

Abstract. Country brand support programs are instruments of open protectionism, which results from unilateral sanctions by foreign countries or acts as a mechanism for direct government support of national producers, creating positive perception by customers abroad and promoting goods and services to foreign markets. However, the long-term preservation of protectionist measures in the national economy leads to the loss of competitiveness by producers and the national economy as a whole. Therefore, it becomes relevant to study the programs of several states in the context of the development of national production and exports, and search for approaches to shaping a comprehensive program of government support for the country brands, which correspond to the main fair competition features in the global economy based on agreements within the WTO. This study is aimed at identifying the feasibility of transforming the "Made in Russia" initiative into a comprehensive country brand government support program. The methodological tools of the studied problem are based on expert and mutual assessments, the Delphi method, mathematical statistics, and graphical modeling. The expert assessment method was used to substantiate the expediency of protectionism for domestic producers to preserve quality and environmental friendliness of export-oriented products in the current conditions that contribute to cultivating the country's positive image. A cause-and-effect diagram (the so-called Fishbone Diagram) developed on the basis of the K. Ishikawa model made it possible to identify the main causes and conditions for shaping a comprehensive program for the country brand government support.

Keywords: country brand; protectionism; government support; national producer; competitiveness; comprehensive program; fair competition

---

1. Introduction

As a rule, the development of national brand support programs, as evidenced by the world practice, is subordinated to two interrelated tasks: national economy restructuring and implementing strategic national tasks related to long-term development and increasing the international competitiveness of domestically manufactured products (Mahrinasari, 2019; Chowdhury, Sanjoy, 2020).

In macroeconomic terms, global financial instability and violation of the fair competition rules in the world economy is a prominent issue (Posen, 2018; Vasiljeva, 2012). In accordance with the global trends, exportability of products is not considered a priority, because programs are auxiliary tools that make goal setting more sound by combining tools to support production and promote the export of products and services into a single complex. In the studies of Szakonyi (2019), the exportability of goods is determined by the quality of the delivered products and price competitiveness rather than by the formation of certain preferences because of the product country-of-origin effect.

According to Workman (2020), the Russian Federation's economy in 2017-2018 had a stable indicator (26.2%) in terms of the export quota, which practically ensured its invulnerability from external factors. In 2017-2018 the geography of exported Russian goods and services was characterized as follows: approximately 54.5% were delivered to European countries; 36.8% to Asia, 3.8% to Africa, 3.4% to North America and 1.2% to Latin America and the Caribbean, excluding Mexico. By 2025, the value of exports is expected to increase to USD 500 billion, including non-resource exports that will make up to USD 200 billion (Knobel, 2018).

The "Made in Russia" initiative to promote Russian goods and brands abroad is designed to confirm fair practices of domestic manufacturers and their reliability as a supplier of quality products. In this regard, the "Made in Russia" provides a general indication of the quality and environmental friendliness of the product. A positive perception of product brands and companies cultivates a strong image of the country, positively influencing consumers' purchasing decision (Kapustina et al., 2017, p. 2).

In brand support programs, the development goals and the transformation of the national economy structure are subordinated to national interests, which entails limitation of the rules of the World Trade Organization (WTO) in terms of promoting the liberalization of the national economy, which directly contradicts the provisions of fair competition for a number of product groups and service sectors in the global economy based on agreements within the WTO.

Vinogradov et al. (2019, pp. 38–39) devoted their research to the issues of trade and economic barriers, and they noted the opposite effect of the sanctions and restrictions imposed by initiating countries. While Bown (2017, p. 1) emphasized losses for "innocent" trading partners. According to Campbell (2018), such decisions resulted in an increase in the value of the importing companies and at the same time the prices for their products, which led to an increase in the cost of certain types of finished products.

According to the authors, it is advisable to provide a combination of short-term and long-term export promotion policies, including the harmonization of domestic and foreign trade policy tools. In the United States, for example, the primary goal of such a program was to create an environment within the country that promoted the consumption of goods and services produced domestically, and only afterwards it acquired the features of facilitating the transfer of real production from abroad to the U.S. In India, this program, along with all tools to support small and medium-sized entrepreneurs, is primarily aimed at creating a sustainable domestic market for

the consumption of domestically manufactured goods and services, and at implementing the task of intra-economic circulation of goods and services between different states of the country. There is no single integrated "Made in Russia" program in the Russian Federation, but industry-specific government programs have been developed that have priority for the Russia's national economy and for economic positioning the country on the global stage.

When comparing consumer preferences for chocolate both in Russia and abroad (Dityashova, 2016), quality, customer awareness (including information indicated on the packaging), authenticity, safety, consumer novelty, image, and consumption price all play significant roles. This study was aimed at identifying effective industry-specific government programs that do not violate the foundations of fair competition in the global economy.

The purpose of the present study is to identify the feasibility of transforming the "Made in Russia" initiative into a comprehensive program to support the country brand. To achieve this goal, it is necessary to solve the following tasks:
- to analyze the positions of the leading countries in relation to brand support programs;
- to identify methods for the formation of versatile tools for implementing the "Made in Russia" initiative;
- to justify the application of governmental protectionist measures under uncertainty in the external environment when exporting products, provided the WTO rules are adhered to;
- to develop a model for the formation of a comprehensive government-supported country brand program aimed at achieving a leading position in international competition.

While conducting the research, statistical data of surveys and empirical studies of scholars, government and marketing agencies were used. The formulated hypothesis of justified protectionism with government support for the country brand was one of the research results for the purposes of achieving liberal values based on compliance with the WTO rules.

The study is original since for the first time it has substantiated the need for protectionist measures in the form of government support for domestic producers of export-oriented products and the implementation of industry-specific programs to achieve the required level of quality and environmental friendliness in accordance with the WTO rules. These measures will make it possible to create a positive perception for the country brand, and to launch a comprehensive brand support program.

To achieve the objectives of the study, the production and export support programs applied in China, the USA and India were analyzed. The authors assessed the competitiveness of Russian goods and services depending on the product country-of-origin effect and the possibilities of using umbrella brands as a factor in promoting Russian products to foreign markets. The effects of the formation of sustainable preferences for Russian products were identified, and proposals were formulated with regard to the formation of versatile tools for implementing the "Made in Russia" initiative. The proposed cause-and-effect model for developing a comprehensive country brand support program will allow it to be adapted to the requirements of improving the national structural policy in the real sector, and achieving leadership in international competition.

Expert and mutual assessments, the Delphi method, mathematical statistics, and graphical modeling methods were employed in this research.

This analysis determined that the "Made in Russia" initiative is essentially an exclusive umbrella brand, and the development of a comprehensive program is necessary for the systemic governmental support. The elaborated cause-and-effect diagram of the structural-logical model to select conditions for the formation of the government-

supported country brand program is of practical importance for the systematization of industry-specific programs to avoid violations of the foundations of fair competition, to solve the structural adjustment problems for the national economy, and to increase the international competitiveness of products manufactured in the country.

2. Literature review

Since the 1990s a discussion has unfolded: some researchers recognize that the product country-of-origin effect affects consumer choice, others deny its importance when making a purchasing decision (Dinnie, 2004, p. 168). Häuble and Elrod (1999, p. 205) are of the opinion that when consumers freely recognize the country of origin of the product, along with its brand, the perception of product quality becomes more positive. Without denying the existence of the product country-of-origin effect in international marketing, Agrawal and Kamakura (1999, p. 259), comparing the quality of similar products of individual firms, found a differentiation in the qualitative characteristics.

Approaches to country brand promotion are quite diverse. A number of scholars considered certain aspects of this issue in the following areas of research. Cowan and Guzman (2018) made a unique contribution to the dialogue about the influence of the country of origin on the effectiveness of the corporate social responsibility (CSR) signal, using the country-of-origin sustainable reputation of the brand (COSR) based on a comparison of sustainability signals and CSR. An interesting conclusion is that consumers' misperceptions about sustainable development affect domestic performance and brand equity. With regard to equity, consumer perception of CSR signals and sustainability contribute to increasing brand value and may be more effective for corporate brands with low or medium COSR ratings.

Heine et al. (2019) developed a model of concept management by facet affiliations of a brand country of origin (COO) for hybrid brands in the context of Chinese luxury brands. Practical conclusions will help brand managers understand which COO facets make a luxury brand "Chinese" one and, on the other hand, how to increase the brand prestige.

The studies by Eng et al. (2016) showed that localization of international business results in different countries-of-origin effects in terms of compliance between a brand of origin and a country of production (COP). Both the country of production and the brand of origin may not coincide, which casts doubt on the impact of incompliance on the brand, consumer ethnocentrism and localization problems, especially when a well-known brand comes from a developed country and COP is in a developing country. The researchers expanded their past studies of the COO effect to find out if COP adversely affected the perception of a consumer product and the buyer's decision to purchase a well-known brand. Their studies showed that a brand origin was especially important for consumers in a developed country when evaluating products, while perceived brand image and price were key factors for consumers in a developing country.

Wang et al. (2020) researched private-label brands as alternatives to national brands. In their opinion, low (vs high) status consumers are more attracted to national brands. Interestingly, this effect appeared only for products low, compared to high, in symbolism. In addition, their results showed that the interactive influence of power distance belief status and consumers on brand preferences was determined by consumers' status consumption needs.

Cristea et al. (2015) examined the main moderating factors of the country of origin and analyzed their impact on consumer's brand perceptions at the cognitive, affective and regulatory levels. They suggested creating an optimal congruence between the country of origin and brand positioning elements.

Bassols (2016) studied branding and marketing in the context of conflict-ridden destinations. He examined the history and development of the country brand in terms of tourism development.

Chan and Ilicic (2019) concluded that conservatism might be associated with stronger attachment bonds to brands. An important role could be played by the political ideology of consumers, which might result in their attachment to the domestic (as opposed to foreign) country of origin.

Kotler and Gertner (2002) considered the extent of the impact made by the country's widespread images on its attitude towards its goods and services, and its ability to attract investment, business and tourists. They also evaluated the role of strategic marketing management in promoting the country's image, attractiveness and products.

The publication of Heslop et al. (2013) presented new insight into the reputational image transfers of mega-events and the places where they occurred. Thus, the Olympic Games in Beijing increased the reputation and image of neither the Olympic brand nor China, whereas in Vancouver they became positive for both.

Bahadir et al. (2015) provided evidence that country-market characteristics moderated the relationship between the complete set of marketing mix elements and brand sales. While distribution and price had the greatest impact in developing and developed countries, product innovations and advertising had a much greater impact in emerging markets compared to developed countries.

Zhou et al. (2010) confirmed that confidence in brand origin identification (CBO) mitigated the influence of perceived brand foreignness on consumer evaluations of brand value. Moreover, the moderating influence of CBO was more profound for local than for foreign brands. Their publication discussed the managerial implications for creating both global and local brands in emerging markets.

At different time periods Schooler (1965), Guina and Giraldi (2014), and Martynova (2018) concluded that there were differences in perceptions of the country of origin by different age groups.

A team of authors headed by Alpysbaeva (2017) studying the effects of integration, calculated the Lafay index and Balassa index for a country to identify the impact of international specifications on the formation of competitive advantages. It was determined that the level of product exportability was not significantly affected by prices, quality and expansion of market volumes within the EAEU.

However, with a large number of studies in this area, the problems of an integrated approach to shaping of government-supported country brand programs based on compliance with international standards and the fundamentals of economic liberalization have not been sufficiently studied. At the same time, the study of the problem of managing country brand promotion in the Russian economy is open and provides for the development of tools that correspond to the basic characteristics of fair competition in the global economy based on the WTO agreements.

3. Materials and methods

The analysis of the "Made in China 2025" program (MIC 2025) confirmed its comprehensive approach to supporting national development challenges. This program is an initiative aimed at securing China's position as a world leader in high-tech industries. MIC 2025 distinctive feature is its reliance on the development of the real

sector of the national economy, which is defined as the basis for China to acquire the status of a world power. This program is targeted at reducing the country's dependence on imports of foreign technologies and investment, stimulating the development of the national economy, relying on domestic innovations, and forming the basis of the Chinese business community that will be able to compete, both domestically and in the world market. China considers the MIC 2025 as a chance to fully integrate into the global reproduction processes and the global value chains, acquiring a sufficiently high share in them (Perskaya, 2019, p. 39).

According to the research of Taguchi (2018, p. 9), a professor at Saitama University (Japan), the share of value added created in China is increasing, while value added in global value chains (GVCs) is decreasing in all production sectors because of foreign production. A study of the process of creating internal added value in China showed that, despite the support of manufacturing industries, the contribution of services (such as trade, utilities, other types of business) is significantly higher with the exception of sectors manufacturing food and metal products, where, according to the Chinese statistics, rural farming and mining are basic industries. Driven by MIC 2025 program, the Chinese economy has entered a phase of restoration of domestic production of value added, stimulating development through domestic consumption. An increase in China's share in GVCs as part of infrastructure projects contributes to large-scale restructuring of the Chinese economy (Yi, 2018, p. 3). The main problem of the "Made in China 2025" program is the toolkit for its implementation, since it applies exclusively administrative methods, subordinate to the decisions of the party bodies.

According to the expert assessment, the economic community of developed countries takes MIC 2025 program quite sharply, seeing it as a threat to fair competition in the world market. The transition from labor-intensive industries and an increase in the share of Chinese manufacturers in value chains with rising wages are determined as the main development paths for China aiming to prevent them from falling into the so-called middle-income trap. The danger of the program, in opinion of experts, is that China is not only becoming a high-tech economy, but, using protectionist methods and ignoring the fairness of competition in world markets, it is attempting to replace Western trans-national corporations (TNCs) in GVCs (Laskai, 2018).

It should also be noted that the MIC 2025 is a program that applies exclusively to the Chinese socio-political system and takes into account the mentality of the Chinese business community. The declaration of its goals and objectives, an indication of possible implementation tools is accompanied by real actions of the local party administrative apparatus, tight control and punishment for untimely execution.

A study of the peculiarities of the American approach to this topic showed that in the United States the main focus is on encouraging the acquisition of American products and increasing employment.

US President Trump's Buy American and Hire American Executive Order of April 18, 2017 was only a legacy of the 1933 Buy American Act and other acts passed thereafter. It contains requirements for the use of products predominantly manufactured within the country when making public procurement, restricting the access of foreign goods to the domestic market, assessing the impact of US free trade agreements with foreign countries and changing the rules for issuing work visas.

The analysis of this Executive Order showed toughening the requirements for public procurement, tightening control over spending of public funds, and increasing import duties on certain types of products. These results made it possible to enhance the consumption of goods produced in the United States, especially steel, iron, aluminum and cement. By revising free trade agreements with Canada, Mexico, and the Republic of Korea, the United States gained more favorable trading conditions for itself. As a result, it was then possible to improve trade surpluses with several other countries. By the summer of 2018, 3.7 million new jobs were created, and for the first

time in the 21st century, more job openings were available in America than the number of job seekers (Acosta, 2018).

The most significant negative consequences of the measures taken were the rise in prices of infrastructure projects; the emergence of difficulties in the sale of products of several industries, including the automotive one; decrease in the foreign direct investment (FDI) inflow; and the growing conflicts between the United States and its trading partners, primarily with China. With regard to the useful American experience in stimulating exports, it is advisable to note the establishment of digital attachés in the diplomatic missions of the United States abroad, which, in the context of the economy digitalization, contributes to the promotion of the export of American goods and services (Revenko & Revenko, 2019, p. 19).

The Make in India program, being a logical continuation of the country's large-scale economic liberalization in 1991-1992, has now acquired a more protectionist focus and aims to create a large domestic consumption market. One of its main tasks is to stimulate the foreign investment inflow in the Indian economy, in the interests of launching and expanding production, gaining access to advanced technologies and increasing export volume. India has also planned to increase the share of the manufacturing sector in the GDP from 15% to 25% by 2025 (Pakhomov, 2014). Practical steps to implement this program include the opening of many sectors of the economy to foreign investment, application of the Automatic route for investment in most of them (i.e., the non-resident of the national company does not require any approval from the government bodies), and simplification of procedures associated with company establishment and business transactions. Industrial clusters representing a modern infrastructure within five corridors are also being built.

As a result, FDI increased significantly in the Indian economy: in 2014-2019 they amounted to USD 335.33 billion, which represents about 51% since 2000. The largest investment inflow was recorded in the 2018-2019 fiscal year totaling USD 62 billion (Make in India, 2020). The largest amounts were invested in telecommunications, computer hardware and software, automotive industry, port infrastructure, power industry, road construction, trade and tourism. In addition, the position of Indian TNCs in international markets has strengthened, and India has become an exporter of capital. Thus, in 2018, the volume of Indian FDI accumulated abroad amounted to USD 166.19 billion, compared to 96.90 billion in 2010 and 1.73 billion in 2000 (United Nations Conference on Trade and Development, 2019, p. 218).

The abundance of cheap English-speaking workforce is a competitive advantage of India, which facilitates the interaction of Western employers with local employees. The factors hindering the successful implementation of the program include the lack of qualified personnel and electric power, the underdeveloped transport infrastructure, the complicated Indian legislation, the difficulties in interacting with government organizations, and periodic conflicts with trade unions.

For the period until 2030, one of the key tasks for India is to intensify activities to ensure the development of long-term planning, and against the background of protectionist support, automation, demographic changes in terms of increasing the number of young people, innovation, and a huge domestic market should become the growth drivers for the national economy. In the context of a sharp change in the business environment for India, it is most important to establish a balance between reality and formulated plans in terms of sustainable development of the country (Somvanshi, 2019).

As for Russia, the analysis of consumer preferences for a number of product groups in January-April 2019, which was carried out using the statistical method based on the data of the Federal State Statistics Service, showed that preferences are mainly given to Russian-made products (66%). Household goods and medical products of Russian

manufacture are chosen by 47% of consumers, with 27% of consumers preferring Russian made shoes, 25% of consumers lean toward domestic clothes, 11.4% opt for domestic cars, and only 3.6% of respondents choose domestic high-tech products. As a result, it was concluded that the quality of the products, rather than the product country-of-origin effect, affects the preference of domestic or imported goods.

While choosing products of a foreign manufacturer, the lower price plays a role for the Russians; this choice is also determined by the traditional perception, rooted in Soviet reality, and implying that a foreign product is always more original, has higher quality and allows the owner to "stand out from the general group" of consumers.

Currently, respondents pay special attention to product safety. Food products are the leaders in the consumption of domestic goods. Out of 170 consumers who prefer foreign-made products, 90.9% choose it because of their higher quality, noting the innovativeness of the products, the best design and the use of new technologies in their production.

Assessment of the competitiveness of Russian goods and services in the domestic and foreign markets depending the use of the product country-of-origin effect, as exemplified by the chocolate market, enabled to conclude that the development/production of the goods and the headquarters of the company should be in the product country of origin. The price for products manufactured in Russia does not play a significant role, but this factor determines the consumer choice for foreign brands of chocolate (Dityashova, 2016).

To justify the need for protectionist measures, it is possible to use the method of expert assessments, since it is impossible to directly measure protectionism data. Therefore, the expert assessment of the results will be the most accurate method.

It seems rational to distinguish representatives of business structures and government agencies that cooperate on an ongoing basis and their area of activity is focused on achieving results related to the promotion of Russian products abroad. When choosing experts for the group, it was assumed that the expert should be authoritative in the issue at hand, and participate in the process being evaluated, or use its results. Top-level managers, their deputies, and head specialists meet these criteria. Mutual assessment of experts can be the basis for an objective selection of the most competent participants. The selection is a kind of sociometric survey, within the boundaries of which the most competent specialist is selected from the respondent's viewpoint. The participants are numbered from one onwards in Table 1.

Table 1. Composition of experts conducting the crossover evaluation procedure

List of representatives of public authorities	List of business representatives
1. A representative of the Ministry of Science and Higher Education.	18. A member of the Chamber of Commerce and Industry of Russia.
2. A representative of the Ministry of Natural Resources and Ecology.	19. A representative of the Russian Union of Industrialists and Entrepreneurs.
3. A representative of the Ministry of Industry and Trade.	20. A representative of the Russian Export Center.
4. A representative of the Ministry for the Development of the Far East and the Arctic.	21. An employee of an engineering company.
5. A representative of the Ministry of Agriculture.	22. The head of a financial business structure.
6. A representative of the Ministry of Construction and Housing and Communal Services.	23. An employee of a brokerage company.
7. A representative of the Ministry of Transport.	24. A representative of a rating agency
8. A representative of the Ministry of Labor and Social Protection.	25. A representative of a consulting company.
9. A representative of the Ministry of Finance.	26. The head of the transport company
10. A representative of the Ministry of Digital Development, Communications and Mass Media.	
11. A representative of the Ministry of Economic Development.	
12. A representative of the Ministry of Energy.	
13. A representative of the Federal Antimonopoly Service.	
14. A representative of the Federal Agency for Technical Regulation and Metrology.	
15. A representative of the Federal Service for Intellectual Property.	
16. A representative of the Federal Customs Service.	
17. A representative of the Federal Tax Service	
In total 26 persons make up 100%.	

Source: the authors

As a result, to take decision on the particular criterion "The need to apply protectionist measures" in accordance with the method of mutual evaluation, it is proposed to select 12 people for the working group. The findings of the sociometric survey were entered into the table; The experts participating in the mutual assessment procedure are indicated by numbers 1-26. In this case, the number 1 in the table cell indicates the choice, "-" is a negative assessment or lack of choice.

To refine the estimates, the weight of each expert was determined. Twelve most competent experts were selected of the total number of candidates; the experts numbered 5, 1, 23, 13, 7, 18, 4, 9, 11, 24, 14, 12 were considered preferable. The expert can give personal self-assessment, which may also be a basis for the final selection of the expert.

Collective methods are also selected along with individual ones. Using the Delphi method is possible in situations where the generality is determined by the parameters of two types – consistency between experts and accuracy.

The authors used an expert assessment in their study taking into account the coefficient of concordance, which is necessary to identify the level of agreement for some series of values of the pre-ranked variables. The main purpose of the assessment is to understand the possibility of the need for protectionist measures on specific grounds (from one or more), and the best option is selected for the set when comparing them. To obtain a qualitative result, the level of agreement in the assessing experts' work is first determined.

The assessment enabled to rank and determine the significance of the experts' properties.

Rank 1 corresponds to the most significant of the experts, rank n denotes the less important one; the rest are within $2 - (n - 1)$.

The problem of allocating a candidate of the i-th place from two entails the assignment of rank $(i + (i + 1)) / 2 = i + 0.5$.

Non-randomness of the consent nature, and the consistency of expert opinions correspond to the coefficient of concordance (C).

Calculation scheme for C:
a) the sum of ranks a_{ij} is determined for each property and group of participants: $j\left(\sum_j a_{ij}\right)$;

b) the average sum of ranks Σa_{ij} is determined for each property:
$$\overline{\Sigma a_{ij}} = 0.5g(n + 1) \tag{1}$$
where g is a number of experts;
n is the number of properties.
$$\overline{\Sigma a_{ij}} = 0{,}5g(n + 1) = 0{,}5 \times 26 \times (8 + 1) = 117 \tag{2}$$
c) deviation of the Δ_i sum of ranks from the average sum of ranks is determined for each property:
$$\Delta_i = |\Sigma a_{ij} - \overline{\Sigma a_{ij}}| \tag{3}$$

$\Delta_1 = |\Sigma a_{ij} - \overline{\Sigma a_{ij}}| = |47 - 117| = 60$ $\qquad$ $\Delta_5 = |\Sigma a_{ij} - \overline{\Sigma a_{ij}}| = |208 - 117| = 91$

$\Delta_2 = |\Sigma a_{ij} - \overline{\Sigma a_{ij}}| = |73 - 117| = 44$ $\qquad$ $\Delta_6 = |\Sigma a_{ij} - \overline{\Sigma a_{ij}}| = |140 - 117| = 23$

$\Delta_3 = |\Sigma a_{ij} - \overline{\Sigma a_{ij}}| = |141 - 117| = 24$ $\qquad$ $\Delta_7 = |\Sigma a_{ij} - \overline{\Sigma a_{ij}}| = |51 - 117| = 66$

$\Delta_4 = |\Sigma a_{ij} - \overline{\Sigma a_{ij}}| = |167 - 117| = 50$ $\qquad$ $\Delta_8 = |\Sigma a_{ij} - \overline{\Sigma a_{ij}}| = |109 - 117| = 8$

d) the sum of the squared deviations for all the properties is determined:
$$S = \Sigma a_{ij}\Delta^2_i \tag{4}$$

$S_1 = 60^2 = 3600$ $\qquad\qquad$ $S_5 = 91^2 = 8281$

$S_2 = 44^2 = 1936$ $\qquad\qquad$ $S_6 = 23^2 = 529$

$S_3 = 24^2 = 576$ $\qquad\qquad$ $S_7 = 66^2 = 4356$

$S_4 = 50^2 = 2500$ $\qquad\qquad$ $S_8 = 8^2 = 64$

$$S = 21\ 842$$

e) the number of repeated ranks of each specialist is calculated, if this happens; the numbers of repeating ranks are not summarized (for example, when repeating rank 5 for three times and rank 3 for two times, 3 + 2 is recorded);
f) if the ranks are repeated, the indicator of their interconnectedness is calculated:
$$T_j = 1 / 2\Sigma (t^3_j - t), \tag{5}$$
where t_j is the number of repetitions for each rank and each expert;
g) in this case the coefficient of concordance is determined as follows:
$$C = \frac{S}{1 / 12 \times g^2(n^3 - n) - g \sum_{j=1} T_{j.}} \tag{6}$$

If there are no coincidence in the ranks with $T_j = 0$, C is determined as follows:
$$C = (12S) / g^2(n^3 - n) \tag{7}$$
$$C = 12 \times 21842 / 676 \times (512 - 8) = 0.76.$$

Thus, the coefficient of concordance varies in the range from 0 to +1 (the case when all experts gave the same assessment for the properties).

If the coefficient is close to 1, we observe a unity of opinion.

Experts were interviewed in the form of questionnaires on the following issues:
1. Does the application of protectionist measures assist in promotion of domestic export-oriented products?
2. Are protectionist measures in demand in the domestic market?
3. Is there an alternative to protectionist measures?
4. Are there government programs aimed at protectionism?
5. Does the application of protectionist measures harm the country's politics, economy, social and ecological environment?
6. Are there any mechanisms for the application of protectionist measures that are different from those currently used?
7. Is it profitable to carry out reforms on the application of protectionist measures, or is it better to keep everything at the previous level?
8. Is it beneficial to take protectionist measures?
9. Is it beneficial to strengthen the role of protectionist measures?

After the interview, expert estimates were summarized using methods of mathematical statistics that allow for combination of these estimates into an integrated assessment of the need for protectionist measures. There is a sufficient number of expert assessment options.

To assess the criterion concerning the need for protectionist measures twelve experts of the working group were interviewed. Their responses were evaluated on a 10-point scale (Table 2).

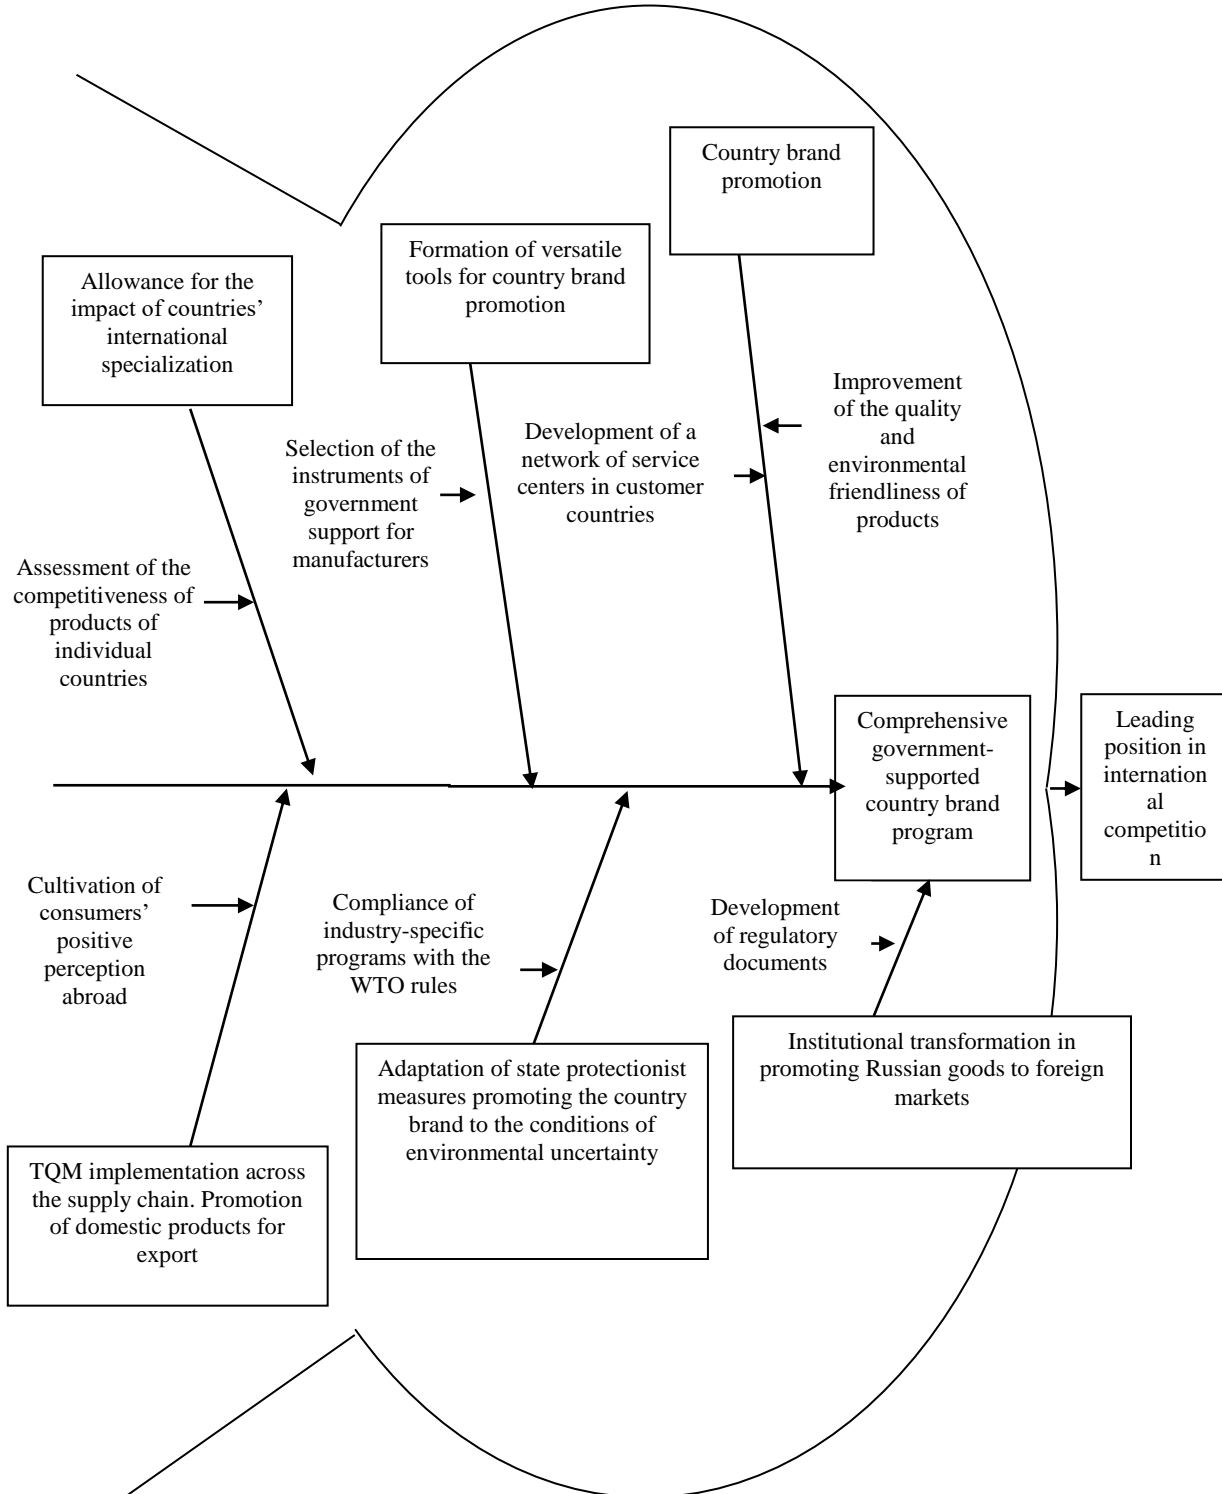
Source: the authors

This research showed that there are prerequisites for the uncertainty of the external environment when exporting products, subject to the WTO rules.

After an expert assessment, the following aspects can be distinguished. The choice of the expert assessment method is justified, since the errors of economic measurements are diverse. The literature refers to more than 80 different types of measurement errors. In the physical measurement, random errors are most common; they may be eliminated by repeated measurements. However, the very possibility of repeated measurements is very problematic due to the irreproducibility of the measurement conditions, as well as an available negative reaction to repeated measurements by both objects and subjects of measurement, leading to the appearance of semantic and pragmatic errors.

By using the Ishikawa diagram, it becomes possible to graphically present the findings and determine the most significant cause-and-effect relationships between the factors and consequences in the problem being investigated. Such a diagram makes it possible to identify the key relationships between various factors and more accurately understand the process under study; it assists in revealing the main factors that have a significant impact on the development of the problem under consideration, and also helps build a graphical model for shaping a government-supported country brand program.

4. Results

The most significant results of the study include:
- stances of the world's major economies regarding brand support programs have been analyzed;
- the need for institutional transformation has been identified – the development of a comprehensive government-supported program to promote the national brand and domestic products in the foreign markets as the follow-up of the "Made in Russia" initiative;
- based on the expert assessment, the use of government protectionist measures in conditions of external environment uncertainty when exporting products has been justified, subject to the compliance with the WTO rules;
- a graphical model has been developed for shaping a government-supported country brand program to achieve leading positions in the international competition based on the approach of K. Ishikawa – "fishbone diagram" (Figure 1).


5. Discussion

The "Made in Russia" initiative is essentially an exclusive umbrella brand, which should ensure the entry of Russian manufacturers into foreign markets. However, it is impossible to achieve this large-scale promotion only by advertising.

In 2019, the Russian Export Center (REC) developed the Rules for the Operation of the Made in Russia Voluntary Certification System, regulating an independent and qualified assessment of the compliance of Russian products, works and services intended for export with the WTO rules.

In addition, the authors, analyzing, in particular, the practice of the USA and Canada in promoting goods to foreign markets, came to the conclusion that the "Made in Russia" brand, focused on compliance of products entering foreign markets with such characteristics as quality and reliability, accessibility and popularity, can be a competitive advantage provided that the implementation of the national image support policy is consistent.

The research results confirmed the hypothesis of the importance of developing a comprehensive government-supported country brand program. It was revealed that for systematic and coordinated state support of the umbrella national brand – with simultaneous support for regional/local brands to bring them to foreign markets, at this stage it seems inappropriate to transform the "Made in Russia" initiative into a comprehensive program without applying the protectionist policy.

This initiative should obtain formation and regulation mechanisms for all components of the reproductive chain of creation and implementation of a foreign trade product. The "Made in Russia" brand can be a competitive advantage if the government consistently implements a national image support policy by promoting and presenting the advantages of domestic products in foreign countries.

Current international economic relations adapt the actions of different states toward the deglobalization processes. The question arises of mutual understanding between the government and business in these conditions. The expert assessment carried out reflects the striving of business and the government for protectionist measures, which is explained by the desire to preserve the profitability of production. However, these measures can be considered forced when the enterprises themselves are unable to achieve environmental friendliness and quality in the production of products, which affects the country brand. Thus, the transition from the "Made in Russia" initiative to a full-fledged comprehensive country brand support program requires protectionist measures aimed at improving the environmental friendliness and quality of domestic products. At the same time, liberal values and compliance with international agreements within the WTO should continue to be a guideline.

The authors believe that further support of the export capacity of Russian industries and the introduction of producers on foreign markets requires orientation towards a liberalization policy. For these purposes, within the framework of the REC or under its auspices, including in the constituent entities of the Russian Federation, it is advisable to establish specialized intermediary companies – foreign trade mediators operating under the terms of commission or commercial mandate agreements, for launching and promoting Russian products to foreign markets. The REC could also conduct quarterly analytical market studies being of potential interest to Russian producers, with the publication of brief recommendations on the website, and provide companies with analytical findings on commercial contractual terms. In addition, the network of REC offices should be expanded in the Russian regions, especially those with exportable industrial potential, including by direct contact with business entities and the organization of the educational process according to the rules, specifics and procedure for exporting products.

To increase the exporters' responsibility regarding their use of an umbrella brand and the implementation of online sales, it is advisable to expand the list of platforms or channels supported by the RECs that ideally meet the needs of small companies seeking to use more than one distribution channel.

Conclusions

The development of civilized relationships that rely on the recognition of fair competition in the global economy, which forms the basis of countries' arrangements within the WTO, reinforces the need to develop comprehensive government-supported country brand programs. These programs make it possible to support companies in domestic markets using protectionist measures that meet the quality and environmental requirements to their products, which contributes to the cultivation of a country's positive image in the international arena.

An analysis of the positions of the world's major economies in relation to brand support programs revealed that the Chinese public enforcement tools for closing down (or moving outside the national territory) inefficient enterprises or those not meeting modernization goals, and lack of acknowledgement from party authorities of the emerging problems of unemployment and social insecurity in citizens, would hardly be applicable in Russia. However, the de-bureaucratization of the processes and terms of connecting newly created companies to electric power networks, orientation toward the use of broadband Internet in the operation of small and medium-sized businesses, and the provision of consulting services by specialized scientific and legal companies to increase labor productivity and export volumes may be relevant.

India's experience in changing the mechanism of VAT refund and hidden subsidy process is of some interest, in particular, the application of the Rebate of State Levies scheme, which involves a partial refund of the Goods and Service Tax (analogous to Russian VAT). The GST is paid by exporters and is not a subsidy.

In summary, it should be emphasized that all government-supported country brand programs are instruments of state regulation or direct management: they are prepared by governments, and the progress of their implementation is strictly controlled by state bodies. The government funds and local budgets are used to implement these programs. Agencies or export centers, export-import and development banks, and specially authorized government officials act as the main entities authorized by the governments of the countries within these programs. The specifics of the program implementation are determined by the socio-political and administrative arrangement of the country.

The researchers substantiated the use of governmental protectionist measures in conditions of environmental uncertainty when exporting products in compliance with the WTO rules. It has been proven that shaping a comprehensive government-supported country brand program requires protectionist measures that create manufacturing conditions for products that have the necessary quality and environmental friendliness in the context of uncertainty around exporting goods in order for that country to achieve a leading status in the global market.

Abstract. Businesses that plan to protect and maintain their assets in increasingly competitive global environment focus on activities that do not create value and reduce the cost of these activities to produce high quality at low cost. Kaizen costing method plays an important role in reducing and eliminating these activities. The main purpose of application in this context is to determine whether the Kaizen costing method has an effect on reducing or eliminating production losses as an activity that does not create value in a transformer producing enterprise. In addition, the effect of Kaizen costing method on production costs was researched in the study, thus saving costs. The effect of Kaizen costing method has been applicated in Kentav Transformer Plant with a semi-structured interview method in order to achieve these goals and objectives, that is, in reducing the activities that do not create value in the production process and saving in production costs. In the research, only the losses in the production process are focused, and activities that do not create value other than production losses are excluded. As a result of the research, it can be said that Kaizen costing method has a positive effect in reducing production losses (defective products, faulty products, wastage and residuum) and saving in production costs.

Keywords: Non-value Activities; Production Loss; Cost Reduction; Kaizen Costing

---

1. Introduction

Today, the changes and developments that occurred both economically and technologically increased the competition even more. In an increasingly competitive environment, the attention of businesses is focused on activities that do not create value and the costs of these activities. Activities that do not create value are unnecessary activities for the business and the customer at the output level and cause additional cost burdens (Dhingra et al., 2019: 792). Activities that do not create value can move businesses away from cost leadership by increasing costs in a global competitive environment. Cost leadership is to produce the same product at a lower cost than competitors without sacrificing quality. Activities that do not create value in businesses cause cost increase and profit losses. These activities that cause an increase in costs should be reduced or eliminated without affecting the product quality and market value. The activities that do not create value in businesses and their costs are becoming more and more important in competing with competitors, and their interest in cost management has increased. Because cost management is not only limited to reducing costs, but also includes other activities across the enterprise to increase profitability (Collatto et al., 2016: 816). Reducing losses in resource use and increasing their effectiveness, making product costs easier to calculate and making healthier decisions in a global competitive environment facilitates cost management (Sowmya et al., 2020: 8284). In order to achieve success in cost management, activities that do not create value should have been focused.

In this study, the effect of Kaizen costing in reducing production losses as the activity that does not create value for producing transformers was researched. The study focuses on production losses as an activity that does not create value. First of all the summary information about non-value activities, production losses and cost management of non-value activities is given in this study. Then, by giving a literature about Kaizen costing, the aim and main components of Kaizen costing are tried to be explained. Finally, the effect of Kaizen costing system on reducing production losses from activities that do not create value was examined by a semi-structured interview technique in a company producing transformers belonging to the private sector and the results obtained were tried to be evaluated.

2. Conceptual Framework

Activities that do not create value can be seen in all managing processes of the business. For this, in any business activity, it should be focused on target activities. If the value-free activity is unnecessary for the business or does not serve the business purpose, it should be eliminated altogether (Kustono et al., 2020: 2215). As an example of activities that do not create value in a business (Shou et al., 2020: 62); unnecessary materials and packaging, poor quality, loss of production, inventory, transportation, control and unproductive working hours can be shown. In the production process, excessive material usage, causing production losses by not producing the desired quality, and unnecessary stocks, lack of control and unproductive waste of time are the activities of the companies that negatively affect the global competitive environment. The most important element that does not create value for the product produced in the production process is waste. Ohno, one of the founders of the full-time production system, defines waste as follows: Defining it as everything that creates no value on the product purchased by the customer and causes an increase in cost (Monden, 2011: 19). Elimination of waste requires reducing or eliminating all activities that do not add value to the manufactured product. It is necessary to avoid any kind of negativity that causes waste, irregularity without overloading workers and equipment during the production process (Kustono et al., 2020: 2216). Activities that do not create value also result from errors in time management and quality system. Production losses in the production process should be carefully examined, the production process should be restructured and the processing time should be further activated to eliminate

activities that do not create value. In addition, non-value-added activity times such as inspection time, transfer time and waiting time should be reduced or eliminated (Shou et al., 2020: 63).

It should not be overlooked that production losses are an important problem that occupies businesses in the global competitive environment. Production losses are the negativities that arise as a result of inadequate machine-equipment, energy, materials, labor use, and management errors in production. These drawbacks reduce profitability and productivity by increasing costs and poor quality. Production losses can be classified according to their occurrence time and qualities. Production losses according to the time of occurrence; It can be divided into three before production, during production and after production. Production losses according to their qualities; can be divided into four as defective products, faulty products, wastage and residuum (Yan et al., 2020: 55). Production losses are revealed at quality control points. Quality checks can be carried out at the beginning, middle and end of production process. With these controls, it is identified whether or not there are predetermined standards and features. While products that meet the standards that pass the quality control stage at the end of production are taken into stock, those who cannot pass the quality control stage are called defective products and faulty products (Ighravwe and Oke, 2020: 114). The defective product can be sold at normal sales price in accordance with the standards by additional processing. The defective product, on the other hand, cannot be converted into a standard product by additional processing and cannot be sold at the normal sales price of a product that complies with the standards. Parts that have a measurable sales value, such as debris, crumbs, etc. in direct materials that enter the production process, are called remainder. The leftovers can participate in the reproduction process or they can be sold at a very low price. Losses that do not have a measurable sales value due to various reasons such as shrinkage, evaporation, and loss from direct materials entering the production process are called losses. In terms of quality, waste can be divided into two as normal and abnormal. While normal waste can not be prevented, abnormal waste can be prevented as a result of increased efficiency. In summary, production losses in businesses negatively affect value formation and competitiveness by causing an increase in quality, cost and dissatisfaction and a decrease in profitability. In order to get rid of this negative effect, activities that do not create value and their costs must be managed very well.

3. Theoretical Framework

Elimination of activities that do not create value is important in terms of achieving sustainable profit purpose in the global competitive environment. These activities lead to decreased profits, higher costs and unnecessary resource consumption. It is inevitable to manage the costs of these activities to the business. In order to manage the activities costs that do not create value, it is first necessary to get rid of the activities negative effects that do not create value in the business. The way to do this is through cost management, which enables the use of business resources more effectively and rationally. Cost management is the effort to provide the necessary information for the efficient use of resources in the products production that can compete in international markets in terms of time, cost, quality and functionality, thereby maximizing the profit of the enterprise and minimizing the costs (Monden, 2016: 67). The objectives of cost management include making accurate product costing, performing product life time performance evaluation, evaluating success, understanding and evaluating processes correctly, controlling costs and helping to implement organizational strategies (Monden, 2016: 68). To put it briefly, cost management supports efforts to eliminate costs that do not create value and to continuously improve them. The costs of activities that do not create value are the costs that do not contribute to this process in terms of product value. As an example of the costs associated with activities not creating value unnecessary stock keeping, production losses, repairing defective production, spare time labor due to various production failures, quality problems can give non-value activity time (Kustono et al., 2020: 2217).

Kaizen costing system, which requires continuous improvement, plays an important role in reducing and eliminating activities that do not create value. Kaizen is a Japanese word that means getting better, improvement, and continuous improvement. It requires the continuous improvement of the work and processes in all areas of life (Monden, 2011: 20). Kaizen costing first emerged as a method used by auto manufacturers in Japan to reduce their production costs (Monden, 2016: 69). In this costing, firstly losses are identified and eliminated for cost reduction (Rof, 2011: 105). Kaizen costing is a cost management technique that is used to reduce costs during the production phase of the product's life cycle and takes periodic profitability targets into account (Ihrig et al., 2017: 225). In other words, Kaizen costing is one of the cost management techniques that focus on continuously reducing costs with all employees' participation during the production (Bozdemir, 2018: 4). Considering the definitions and theories listed above, it is understood that Kaizen costing has two main purposes (Macpherson et al., 2015: 5):

• Applying the Kaizen philosophy to the production process to achieve cost reduction

• To avoid waste by extracting the activities that does not create value from the production processes.

However, it is seen that there are five main components of Kaizen costing system. They are: Full Time Production, Work Tools, Total Productive Maintenance, and Suggestion System Poke Yoke (Macpherson et al., 2015: 5-7).

4. Literature Review

Chen (2015), in his study comparing traditional and Kaizen costing, aims to reach the cost performance standards where traditional methods adopt the understanding of cost control system, stagnation of production conditions and cost. It is stated that Kaizen costing adopts a cost reduction system and assumes continuous improvement in production. The purpose of Kaizen costing is to reach cost reduction targets. In the research carried out by Ihrig et al. (2017), 86% of the enterprises use activity-based costing system, 7% use product life cycle costing and 1% Kaizen costing system. Normal and abnormal wastage costs are taken into consideration in the majority of enterprises, and wastage costs are mostly attributed to the products. Bozdemir and Orhan (2012) conducted a survey on the applicability of Kaizen costing method in the main and sub-industry companies in the Turkish automotive industry. The companies participating in the research responded to Kaizen Costing Method with a rate of 47.0% and another method similar to Kaizen Costing under a different name in our enterprise and with a rate of 13.7% is a method applied in the production stage in our enterprise. Hacıhasanoğlu (2014) has achieved a 29% improvement in the production amount with the Kaizen activities carried out in the enterprise operating in Kayseri in order to apply the Kaizen costing method in the furniture industry and create awareness in this regard. Rodriguez and Lopez (2012), conducted a survey with 87 of 154 manufacturing companies registered Activity Based Costing, Target Costing, Kaizen Costing, Quality Cost System, Just In Time Production Environment Costing, Product Life Period Costing systems and the companies that apply cost management systems to determine which purposes they apply, and why businesses that do not apply, determine from 154 registered companies in the Stock Exchange. While the companies that apply Kaizen Costing apply with the aim of decreasing the total processing time, constantly control the production costs and reduce the production costs with the most continuous improvement efforts, the companies that do not apply Kaizen Costing do not apply due to the lack of sufficient knowledge about the application. Okutmuş and Ergul (2015) conducted field research in a five-star hotel company in Antalya regarding target costing, value analysis and Kaizen costing methods. In Kaizen costing application, it was found that the accommodation company should make a cost minimization of 1.210.000 TL in total, in order to reach the target costs, in other words, Kaizen cost target determined in order to achieve the target sales price and target sales volume in 2014. In addition, in the study, it is suggested that in the use of these methods, they should recruit and / or train qualified personnel who will apply these methods correctly. Collatto and others (2016) aimed to identify lean accounting practices consistent with strategic cost management in companies in the industrial sector working with lean manufacturing. As a result, they proved that the companies

surveyed continue to use traditional costing methods. Finally, they also proved that companies are more involved in lean manufacturing practices than lean accounting, filling a gap in the literature on the subject. Gül and Gül (2017), in their study on new methods of reducing costs in industrial food establishments, investigated what measures enterprises take to reduce costs. In order to increase the profitability of the enterprises, the most important ways they use are to reduce raw material costs and improve the current market. But to increase profitability, increasing quality, increasing price and reducing labor costs are not considered as a tool. Santos and others (2018) focused on the analysis of quality costs in the automotive industry, including a bus manufacturing company. Its main purpose is to improve the quality costs indicator by providing tools to assess the cost of failure in the manufacturing process. Kaizen-lean principles were used as methodology. Kurebwa and Mushiri's research (2019) includes the design and simulation of an integrated steering system for Sport Utility Vehicles for Toyota. In keeping with the spirit of Kaizen, in this article, they explored possible improvements in the transportation capabilities of sport utility vehicles in an energy-efficient way. As a result, it has reached three key conclusions: improved vehicle use, sustainable steering system development and autonomous driving. If a company wants to provide control and efficiency in Kaizen costing, deviation analyzes should be made for continuous improvement. If the expected savings are achieved, there is no deviation. Deviation is positive if higher savings than expected (Dhingra et al., 2019: 795).

To put it briefly, Kaizen can be considered as an effective tool for eliminating activities that do not create value in the production process in enterprises. Because this costing can be focused on the cost of direct first substance and material, direct labor and general production, as well as only one of them. Kaizen costing is a cost reduction method that helps to eliminate activities that do not add value to the product in the production process by continuous improvement.

5. Application

5.1. Purpose of the Research
The main purpose of this application is to determine whether Kaizen costing method has an effect on reducing or eliminating production losses as an activity that does not create value in a company producing transformers. In addition, by investigating the effect of Kaizen costing on production costs, it is aimed to save costs. In order to realize these goals and targets, the production losses were focused from the activities that did not create value in the production process, and other activities that did not create value were excluded.

5.2. Scope of the Research
Within the scope of the research, the effect of Kaizen costing method applied on production costs was carried out in JSC "Kentav Transformer Plant". JSC "Kentav Transformer Plant" AŞ is one of the important organizations of the Kazakhstan industry sector. Here, focusing on production losses from activities that do not create value in the production process, other activities that do not create value are excluded. The reason for the industrial sector to be considered within the scope of the study is the importance of the industrial sector for both the Kazakhstan economy and Central Asia. In the selection of this enterprise in the industry sector it is very important that business management is open to change and innovation. In addition, their interest in both of accounting information system and the provision of the information needed the emphasis placed on institutionalization as the first private transformer-producing business was effective. Therefore, only the enterprise operating in the production branch has been selected for the purpose of the application in the research and it has been included in the application.

5.3. Information About the Sample Business

JSC "Kentau Transformer Plant" (hereinafter– JSC "KTP") is known as the leading Kazakhstan producer of the transformer equipment of wide application delivered for all branches of economy, including power industry, metallurgy, mechanical engineering, transport, oil and gas complex, housing and communal sector. JSC "KTP" was founded in 1959. Since 2005 JSC "KTP" is a structural subdivision of the company "Alageum Group" created to unite several stably developing enterprises in order to promote high-quality electrical equipment in the CIS markets. Today JSC "KTP" occupies a leading position on the market of Kazakhstan for the supply of transformers voltage 6-10 kV with a market share of more than 60%.

For last years, the list of plant production reached more than 400 names. The main strategy of JSC "KTP" is delivery to the market of the best electro technical production conforming to requirements of consumers for quality, the price, delivery conditions and the provided service. Today, the plant is rightfully the leader of domestic electrical engineering, a leading manufacturer of transformer equipment. The equipment with the JSC "KTP" brand reliably works in all territory of the CIS and Central Asia. JSC "KTP" in the course of modernization was rid of "loose" production equipment of the USSR and switched to the latest high-tech equipment of leading Western and European companies, which are considered as one of the best in the world. The share of local content in the manufacture of equipment is 85%. The recommended period of technical operation of transformers is 25 years, but in fact, with proper operation and timely maintenance, the transformer operates uninterruptedly for 40-50 years (https://alageum.com/en/predpriyatiya/ao-ktz).

This enterprise is one of the first private sector enterprises of Kazakhstan in the industrial sector and annual sales revenue is around 22.76 billion tenge with 2019 data. According to data captured December 2019, 1 252 personnel are employed in 2 shifts. While many private sector enterprises terminate their activities until 2019, this business continues to grow. In this enterprise, production costs are calculated according to the full cost method in terms of scope. In this calculation, actual figures are used, and in this enterprise, the costs are distributed based on volume, and the stage cost method is applied according to the production technique (shape).

5.4. Research Methodology

Within the scope of the research, in order to get ideas about the subject, in-depth interview techniques were selected from qualitative research, which is a rich data collection management. The basic method used in the realization of the study was carried out using semi-structured interviews with the relevant managers and employees of the business. In this semi-structured interview as manager; 19 managers were interviewed such as factory manager, raw material procurement manager, business manager, personnel manager, purchasing manager, accounting manager, production manager and logistics-distribution manager. Also regarding the transformer production process, 30 people responsible for raw material purchasing and analysis, holding, pressing (curling), dyeing, drying, classification, packaging, transportation, laboratory and technical works were interviewed. The in-depth interview took 40 minutes with the factory manager, about 30 minutes with other managers and an average of 20 minutes with each employee. Interviews were carried out in December 2019. In addition, a questionnaire was applied to all managers and other personnel in the company and other employees. Due to inconsistencies and errors in the answers, some questionnaires were eliminated and 249 questionnaires were taken into consideration in the study.

Thanks to these interviews and surveys, answers to the questions were sought and the opportunity to access new information was obtained in reducing Kaizen costing activities that do not create value. In addition, the stages in the production process are observed exactly. In the study, it was preferred to collect data from the company's annual reports, internal documents, industry reports and other studies.

6. Findings and Evaluation

Data related to managers, unit officers and employees participating in the interview and survey study are shown in Table 1. According to Table 1, 5 of the participants are the top managers, 14 - factory managers, 30 - unit or department officers and the remaining 200 are other employees. The important thing in this table is that 20% (49 people) of our respondents are managers and people who work responsibly. Here, it is understood that all of the managers related to Kaizen costing have detailed information, while 67% of the employees in the production process have sufficient information and 33% have general knowledge. In addition, all of the interviewees have seen the performance of the machines in the facility sufficiently and stated that the operation is absolutely innovative, otherwise it will not be possible to survive in a violent competition environment and continuity can not be achieved.

Table 1. Positions of interview participators

Positions	Number	%
Senior Managers	5	2,0
Plant Managers	14	6,0
Unit Officers	30	12,0
Other workers	200	80,0
Total	**249**	**100**

Defective product and wastage occur as production losses in the sample enterprise. It is not taken into account because the defective product is small enough to be said to be absent. Production losses in the sample business are shown in Table 2 below and the level of loss in the business is shown in Table 3. Total production consists of defective and non-defective products totals. Waste and waste is 14% of the total production. Production losses in the enterprise are within normal limits. The share of work teams is important in the absence of a defective product. The most important reason for the defective product to occur is power outages caused by outside the enterprise. Waste is in the process of purchasing, holding and transporting raw materials and in production. Waste amount can be considered normal considering the industry sector. It is an important problem that waste in the enterprise is not used in another production process.

Table 2. Production Losses of Sample Enterprise by Years

Production Losses*	2015	2016	2017	2018	2019
Defective Products	1 348,75	1 468,60	1 593,00	1 728,00	1 934,60
Faulty Production	-	-	-	-	-
Wastage	1 926,78	2 098,00	2 275,71	2 468,57	2 763,71
Non-Defective Products	12 138,75	13 217,40	14 337,00	15 552,00	17 411,40
Total Products	**13 487,50**	**14 686,00**	**15 930,00**	**17 280,00**	**19 346,00**
*million tenge					

According to Table 3, equipment inefficiencies in the sample enterprise come to the median with a rate of 39.0%, labor inefficiencies with a rate of 36.5%, material and energy losses with a rate of 31.7%. It is not possible for the enterprise to reach the target cost with these losses during the production phase. It is possible to prevent mistakes and defects that cannot be foreseen in every business. In this case, the implementation of the Poka Yoke system,

which is the main component of Kaizen Costing, is inevitable. In this way, resource and usage planning can be done correctly. The production process will contribute to the reduction of activities that do not add value to the relevant planning, practices, controls and necessary measures.

Table 3. Level of losses occurring in enterprise

Losses Occurred	Allways		In General		Sometimes		Rarely		Never		Total	
	n	%	n	%	n	%	n	%	n	%	n	%
Equipment inefficiencies	8	32,0	39	15,7	97	39,0	47	18,9	58	23,3	249	100
Labor inefficiencies	13	5,2	39	15,7	91	36,5	65	26,1	41	16,5	249	100
Material and energy losses	12	4,8	44	17,7	79	31,7	69	27,7	45	18,1	249	100

In Table 4, production costs of the sample enterprise by years are shown in detail. All of the interviewees stated that saving is inevitable in every environment where waste. They stated that, regarding the cost factors, savings can be made at the following rates.

Direct First Substance and Material Expenses are the expenses that directly enter the body of the product and whose technical and economic value can be determined very easily (Savcı, 2012: 130). The share of direct item and material expenses in total production costs (16 444, 10 / 19 346, 00) in our sample business is approximately 85%. 80% of the interviewed people can save at least 10-15%; 20% stated that thanks to a good policy, the saving rate can be approached to 0%.

Direct Labor Expenses are related to production expense locations and are the use of value that can be directly loaded into production and form the product, changing its shape, structure and status (Savcı, 2012: 136). The share of direct labor expenses in total production costs (967, 30 / 19 346, 00) in our sample business in 2019 is approximately 5%. 87% of the interviewed people stated that they could not save and 13% stated that they could save 2-3%.

General Production Expenses, on the other hand, refer to all the use of value related to production, other than direct raw material and material costs and direct labor costs. These value uses are those that cannot be directly loaded on the manufactured product (Savcı, 2012: 138). The share of general production expenses in total production costs (1 934, 60 / 19 346, 00) in our sample business is approximately 10%. 80% of the interviewed people stated that 5-6% savings can be made if natural gas is used as fuel, and 20% can save 10% if natural gas and quality material input is used.

Table 4. Production Costs of Sample Enterprise by Years

Cost Elements *	2015	2016	2017	2018	2019
(+)Direct First Material and Material Expenses	11 464,375	12 483,10	13 540,50	14 688,00	16 444,10
(+)Direct Labor Costs	674,375	734,30	796,50	864,00	967,30
(+)General Production Expenses	1 348,75	1 468,60	1 593,00	1 728,00	1 934,60
(=)**Total Production Cost**	**13 487,50**	**14 686,00**	**15 930,00**	**17 280,00**	**19 346,00**
Total Production Number **	20 750,0	20 980,0	21 240,0	21 600,0	22 760,0
Unit Cost	0,650 tenge/piece	0,700 tenge/piece	0,750 tenge/piece	0,800 tenge/piece	0,850 tenge/piece
*million tenge **piece					

The participation of the value chain members in the cost estimation and cost reduction process in the sample business is shown in Table 5. According to this table, the value chain members generally take part in the cost estimation and cost reduction process with a rate of 40.6% from the accounting-finance department, and they usually participate in the sales and marketing department at a rate of 26.5%, product planning-design engineering and research. And they never attended at the rate of 34.1% from the development department, they usually attend at the rate of 30.9% from the purchasing service, they never attend at the rate of 32.5% from the production part, 29.7% from the quality control part. They explain that they generally attend to a certain extent, sometimes participate in distribution and logistics with a rate of 27.7% and suppliers sometimes attend with a rate of 36.5%.

Table 5. Value chain members' participation in cost estimation and cost reduction

Value Chain Members	Allways		In General		Sometimes		Rarely		Never		Total	
	n	%	n	%	n	%	n	%	n	%	n	%
Accounting / Finance	50	20,1	101	40,6	49	19,7	18	7,2	31	12,4	249	100
Sales and marketing	43	17,3	66	26,5	57	22,9	38	15,3	45	18,1	249	100
Product Planning / Design Engineering-R&D	27	10,8	55	22,1	51	20,5	31	12,4	85	34,1	249	100
Purchase	54	21,7	77	30,9	56	22,5	33	13,3	29	11,6	249	100
Production	34	13,7	62	24,9	45	18,1	27	10,8	81	32,5	249	100
Quality Control	39	15,7	74	29,7	55	22,1	40	16,1	71	16,5	249	100
Distribution / Logistics	18	7,2	53	21,3	69	27,7	46	18,5	63	25,3	249	100
Suppliers	20	8,0	53	21,3	91	36,5	54	21,7	31	12,4	249	100

Information about the application level of 5S, which is a management philosophy of Kaizen Costing System in the sample business, is shown in Table 6. According to Table 6, it can be said that the classification and standardization is good in the implementation of 5S in the sample enterprise, and the regulation, cleaning and discipline is very good. This situation increases the application level of Kaizen Costing methods for the enterprise. In addition, as a result of the structured interview and observation, it has been seen that the main components of Kaizen costing can be easily applied to all activities of the enterprise.

Table 6. Application level of 5S in business

5S	Best		Good		Middle		Worse		Worst		Total	
	n	%	n	%	n	%	n	%	n	%	n	%
Sort	72	28,9	130	52,2	39	15,7	6	2,4	2	0,8	249	100
Set in order	105	42,2	99	39,8	41	16,5	2	0,8	2	0,8	249	100
Shine	120	48,2	91	36,5	31	12,5	4	1,6	3	1,2	249	100
Standardize	79	31,7	110	44,2	46	18,5	11	4,4	3	1,2	249	100
Sustain	123	49,4	84	33,7	36	14,5	4	1,6	2	0,8	249	100

Conclusion and Recommendations

It is seen that the effect of Kaizen costing on reducing production losses from activities that do not create value has been adopted by the continuous improvement approach in the enterprise. With the continuous improvement approach, it is aimed to increase the efficiency of activities that create value, and to prevent unnecessary losses by reducing or eliminating activities that do not create value. In the enterprise, activities that do not create value related to the production process are encountered before and during production. While activities that do not create pre-production value appear as wasted time during supply and purchase, in the production process, it causes production losses due to reasons such as breakdown of machines and power outages.

Another remarkable subject about the sample business is workmanship. Here, special attention is paid to craftsmanship and attention is paid to the training and continuity of workers working in production. Even the unskilled workers are preferred by the local people who have knowledge about transformer production. In this way, the continuity of workers to work is maximized and production losses due to workmanship are minimized. The point of view of the sample enterprise over the overall production costs is also strategic. It is aimed to reduce the production losses caused by the breakdown of the machines in the production process by paying due attention to maintenance and repair.

It can be said that the exemplary enterprise has a strategic perspective regarding activities that do not create value and especially production losses. However, the most important thing to be done directly related to the first substance and material expense is the necessity to establish a standard purchasing policy regarding this cost element, not only within the factory, but also with suppliers (preparations). In this way, it is possible to save 15% in direct raw material and material expenses.

Suggestions regarding the effect of Kaizen costing system on reducing production losses have been developed by considering the answers of the questions asked during the semi-structured interview and survey study in the sample business;
- Kaizen Costing Technique should continue to be implemented by all employees at all business levels;
- Importance they attach to the implementation of 5S, which is a management philosophy, should continue;
- It is absolutely necessary to prevent unforeseen mistakes and defects, to minimize them and therefore to realize the necessity to apply Poka Yoke system;
- Cost reduction efforts for new or existing products should be carried out at both the product design and production stages.

As a result, throught the Kaizen costing, the efficiency of activities that create value can be increased and the effect of activities that do not create value can be reduced or eliminated in this exemplary enterprise producing transmormates. Briefly, with the application of Kaizen costing, activities that do not create value and cause waste in the production process can be eliminated and a positive effect can be made on production losses and production costs.

In summary terms, it is possible to apply the main components of Kaizen costing in the sample business. In this way, unnecessary stock availability, production losses, wasted time and quality problems due to various production failures can be reduced. Unnecessary transfer time and waiting time can also be eliminated. By focusing on the standards in the production process, continuous improvements can be made and internal cost reduction and productivity increase can be achieved. In this way, an advantage against its competitors can be obtained in the intense competition environment in the tea industry.

Findings obtained in this research are qualitative results. Therefore, generalization cannot be made. In further studies, the study can be supported by conducting quantitative research on the subject. In order to determine the effect of Kaizen costing on activities that do not create value more realistic, it is necessary to focus on activities that do not create value other than production losses.

Abstract. Education can play an effective role in building social responsibility in a community which can help to reduce pollution emissions. This present research investigates the effects of education, energy consumption and economic growth on CO₂ emissions in Saudi Arabia using data of a period 1971-2014. We find that primary education could not affect CO₂ emissions, but, secondary education has a negative effect while energy consumption has a positive effect on CO₂ emissions. In the long run, an inverted U-shaped relationship is found between CO₂ emissions and economic growth and Kingdom is found at first stage. Hence, economic growth is responsible for environmental degradation. We recommend to enhance the secondary education to improve the environment of the Kingdom and to use cleaner source of energy to avoid negative environmental consequences of economic growth.

Keywords: Education; Economic growth; Energy consumption; CO₂ emissions

1. Introduction

The idea of environmental stability and eco-friendly economic activities has been a hot topic of debate across the world. Many countries from the developed, developing, and under-developed parts of the world are making an effort so they can identify better and smarter ways to be more sustainable. Greenhouse gases are in the middle of the discussion of environmental talks and debates since it is one of the biggest causes of environmental degradation. One aspect of this endless discussion of the determinants of pollution emissions is the contribution that education and human capital may play in this domain. The level of education can help improve the economic condition of any economy while it also raises environmental awareness among the common people. On the other hand, considering that the EKC exists in a country, there is a need to expedite the process of economic growth so that the country can reach the cut off from where the environmentally degrading effects of economic activities start to decline and the ecological footprint starts to recover. In that instance, if education can improve the economic condition of a country which eventually reduces pollution, it can be easily said that education can be used as a major source of reducing pollution in a country.

The idea of the environmental Kuznets curve (EKC) is popular in the field of environment and energy as well and the concepts argue about the inverted U-shaped relationship between environment and growth (Grossman and Krueger, 1991). It means that economic growth pollutes the environment in the first phase of EKC. In the second stage, demand for a cleaner environment may increase with further economic growth. Theoretically speaking, the idea of this sort of a relationship does make sense because in many cases, as a country makes economic progress, it has to rely on a lot of energy consumptions at the first stage of development, most of which have to do with the industrial, construction and manufacturing sector. All of these developmental activities may increase CO_2 emissions and pollute the environment due to higher energy consumption. Something similar was provided in a study by Eluwole et al. (2020) in which they mentioned that a 1% increase in kg oil equivalent of energy consumed can increase environmental degradation by 0.918%.

On the other hand, Bekun et al. (2019) mentioned that renewable energy consumption can lead to an improvement in environmental quality and fossil fuel can lead to deterioration in the environmental portfolio of a country. Alola et al. (2019) investigated the sixteen coastline Mediterranean countries using data 1995-2014 and found the bidirectional causality between renewable energy and CO_2 emissions and between food production and CO_2 emissions. They concluded that food production contributed to environmental degradation and inflation helped to reduce CO_2 emissions. Moreover, Alola (2019) investigated the effects of the policies on the CO_2 emissions in the US using quarterly data of 1990-2018. He found the positive effects of income, renewable energy consumption, trade policy, financial regulation, and monetary policy on the CO_2 emissions in both the long and short run. However, the effect of migration policy is found insignificant. Mahmood et al. (2019) found the asymmetrical effects of trade openness on the CO_2 emissions and increasing trade openness contributed to the CO_2 emissions but the effect of decreasing trade openness is found insignificant.

There is limited research on whether education has to play a role in EKC or not. Balaguer and Cantavella (2018) argued that the energy resources of a country depend on the human capital and educational systems a lot and education can play a significant role in an economy on many levels. With an expansion on the EKC, the study investigated data from 1950-2014 and it was hypothesized that a higher educational level can offset the negative effects of CO_2 emissions in the economy. They provided evidence that an increased level of education could offset the environmentally degrading effects of CO_2 emissions. It proves that an expansion in the educational system can compensate for CO_2 emissions that have resulted from income growth. It was suggested that since income growth is not as easy to manage, promoting education is always a good idea since the environmentally-

degrading effects of economic activities can then be offset without having to make things worse in the first place. With education making its way up with economic growth, sustainable environmental objectives can be met without having to enforce a stringent environmental policy.

There is a limited number of studies that analyze the relationship of various educational levels on the environment while testing other economic variables. The EKC is well investigated in the Saudi environment literature (Omri et al., 2019; Mahmood et al., 2018; Mahmood et al., 2019) but a role of education on the CO_2 emissions is still missing in the Saudi literature particularly. Ignoring the EKC, Mahmood et al. (2020) found that oil, non-oil income, and urbanization were increased the CO_2 emissions in Saudi Arabia while gasoline prices helped to reduce emissions. Although, Omri et al. (2019) have probed the role of human development on CO_2 emissions in Saudi Arabia and found an insignificant effect. Human development carries health, education, and income indicators. In which, education looks more meaningful in determining the pollution than that of health and income indicators. Therefore, the purpose of our research is to isolate the effect of education on the CO_2 emissions in Saudi Arabia ignoring other dimensions of human capital.

2. Literature Review

There is good literature on testing the EKC hypothesis in Saudi Arabia. For example, Mahmood et al. (2018) investigated EKC in Saudi Arabia and found that Saudi Arabia is found in the first phase of EKC. Further, they found that Financial Market Development (FMD) has asymmetrical effects on CO_2 emissions, and reducing FMD can lead to environmental degradation. Moreover, a decline in energy consumption can reduce CO_2 emissions. In another dimension, Mahmood et al. (2019) investigated the effects of the agriculture sector on the CO_2 emissions of Saudi Arabia and also tested the EKC hypothesis using the period 1971-2014. They found the EKC in the testing but the turning point indicated that Saudi Arabia was in the first phase of EKC. They also found the inverted U-shaped relationship between agriculture development and CO_2 emissions. However, the negative effect of the agriculture sector on CO_2 emissions was corroborated. Hence, the agriculture sector showed a pleasant environmental effect in Saudi Arabia.

Omri et al. (2019) conducted a study on Saudi Arabia to answer two major questions; one is about the EKC and the other is analyzing the effect of trade openness, FMD, human development, and FDI on the environment. The analysis aimed to investigate one of the most crucial concepts in the field of environmental economics. It was concluded that FDI, trade openness, and per capita income play a role in environmental degradation in the Kingdom which means that a higher national income, more foreign investment, and open trade relations with the neighboring countries can lead to higher emissions and degrade the environment. But, the effect of human development is found statistically insignificant. The EKC was validated and they indicated that as the country makes more economic progress, the negative effects of this environmental degradation can be offset. Mahmood et al. (2020) found the positive impact of industrialization and urbanization on the CO_2 emissions in Saudi Arabia. Alkhatlan et al. (2020) investigated the oil concentration effects in Saudi Arabia and found the negative impacts of exports and employment concentration on economic growth. Moreover, Alkhateeb and Mahmood (2020) explored and found that oil price was responsible for energy depletion in the GCC region with asymmetrical effects of magnitude. This relationship was also true in each country analysis and most of the effects were found elastic as well. Mahmood and Furqan (2020) investigated the role of oil rents on emissions. They found that oil rents have a U-shaped relationship with N_2O, Inverted-U-shaped relationships with CH_4 emissions, and linear positive relationship with CO_2 emissions.

Other than Saudi Arabia, some studies have also focused on the role of human capital in determining the environment. Zafar et al. (2019) put forward an argument that investment in the natural resources sector, human

capital, and FDI were associated with an ecological footprint in the US using data from 1970-2015. They found that energy consumption due to income growth could lead to a positive effect on the ecological footprint which deteriorated the environment. Granger causality showed a bidirectional relationship between energy consumption and ecological footprint. A similar relationship was shown between ecological footprint and economic growth and ecological footprint and human capital as well. It was suggested that the country puts more investment in human capital so that natural resources can be used more efficiently and the ecological footprint of the country could improve with time. Ma et al. (2019) worked on China using period 1995-2015 and it was mentioned by that human capital had a long-run quadratic effect on the environmental regulations which indicated that with time, the effect of education on environmental policies could improve and help to improve the ecological footprint of the country. For the sustainable development of a country, it is crucial to incorporate the education sector and focus on human capital so that the effects can be widespread. Zamil et al. (2019) explored that trade openness and economic growth had a positive contribution to the CO_2 emissions in Oman. Education is not only beneficial for the environment but has also been helpful to improve moral upbringing and to reduce social unrest (Furqan and Mahmood, 2020). Literature also signified the role of human capital and innovation to achieve sustainable development and sustainable competitive advantage (Pangarso et al., 2020; Prasetyo and Kistanti, 2020).

Yao et al. (2019) conducted a panel analysis of OECD countries to scrutinize the role of human capital on energy consumption using data 1965-2014. The results of the study provided a piece of evidence that human capital is responsible for reducing energy consumption by almost 16% which is a dramatic decline. They segregated the energy consumption matrix into two clean and dirty sections. It was shown that reduction of 17% of dirty energy consumption and up to almost 86% of clean energy consumption were associated with human capital and almost this much percentage of clean energy consumption could be improved with higher education and human capital investment as well. The results of their study suggested that countries focusing on reducing their energy consumption and making it sustainable should focus on investing in human capital. This is a win-win situation for any country since not only the natural resources can be saved, a higher level of human capital can result in economic growth which benefits the country for a long-term.

Ponce et al. (2019) analyzed the labor market returns and human capital investments and connected their role with the energy sector in an empirical study using the period 2010-2016. The labor income and educational sector were seen to play a significant role in shaping the behavior of people towards the energy and environmental sector. While poor environmental stance and policy were a result of multiple dynamics including lack of awareness and education could take a step further in helping different communities with changing their behaviors towards the sector so that overall household behavior could be changed. Using a period 1974-2014, Bano et al. (2018) found that human capital affected the CO_2 emissions in Pakistan. Both variables seemed to share a long-term relationship. Looking at these variables through the perspective of economic growth, it was also argued that while human capital investment increased in the country, CO_2 emissions could be reduced without having to give a push to economic growth. Both major variables also shared a two-way causal relationship in the long-run. Further, they argued that interactive learning environments could be used to improve the levels of understanding of the general public regarding CO_2 emissions and accumulations in a region as it could help in conducted human-facilitated sessions that could raise awareness and could remove any barriers from the learning structure. Without having to implement a strong macroeconomic policy, just educating on a small scale could make a huge difference as well (Qudrat-Ullah and Kayal 2018).

There is limited literature available on the role of education on CO_2 emissions. According to Shields (2019), higher education can be strongly linked to global climate change. International student mobility was considered as a major determinant of greenhouse gas emissions on an international level. The results indicated that although global CO_2 emissions across the world are experiencing some significantly large increase emissions per

international student have declined which is explained by changes in student mobility patterns. In a theoretical setting, the fact cannot be denied that higher education can lead to changes in the economic and social structure of a community. As a result, other segments in the region can also improve which is something that needs to be considered while devising educational policies related to higher education of international students. Taylor et al. (2007) mentioned in their study that in commercial areas, educational campaigns helped to reduce storm-water pollution to a wide extent. Although the study did not connect education to CO_2 emissions through economic growth, it was argued that higher education activities and more awareness campaigns helped to play a role in reducing pollution which magnified the importance of improving human capital and knowledge management platforms. On a practical level, countries aiming to reduce their ecological footprint should focus on educational activities more often so that they can cover some part of the pursuit through these initiatives.

Bekaroo et al. (2019) provided a unique talk on the topic of education, income growth, and their link with CO_2 emissions. They argued that sustainability change agents of higher education institutions could have the responsibility of using the platform to raise this issue among the student community. In that instance, teachers in these higher educational institutions could spread awareness in the student community and inform them about the harmful effects of these pollutants. If conducted on a long-run basis, this conversation could become a major reason for a structural change in a country and could directly influence the environment. The study took place in Mauritius and data from 440 employees of higher educational institutions was used. The results suggested implementing strong policies that could help to incorporate the educational sector in the environmental policy to a more prominent extent.

One aspect of human capital is health and some studies worked on the effect of health variables on pollution emissions. For example, Chaabouni and Saidi (2017) analyzed 51 countries to explore the association between CO_2 emissions, health spending, and income growth. Three groups of countries were selected according to income classification and data from 1995-2013 were used. A causal relationship was explored between the three variables under analysis. Additionally, unidirectional causality was also seen from CO_2 emissions to health spending levels in all countries except low-income ones. It was suggested that these countries focus on energy consumption and productivity, and also the efficiency of energy since it provides more pathways for long-term growth and can help to create a good balance. Alola and Kirikkaleli (2019) analyzed the relationship between environmental quality and renewable consumption while the concept of immigration, consumption, and healthcare was also considered. The rich analysis studied the long and short-term relationship between CO_2 emissions with the factors mentioned above. It was seen that immigration and healthcare sector amendments lead to higher CO_2 emissions in the US. Further, Alola (2019) mentioned that renewable energy consumption and real income in a country put an impact on the carbon emissions of the country but health has an insignificant effect.

The recent literature signifies the importance of education, human capital, and human development in determining pollution emissions. Most of the literature on this issue focuses on the role of human capital and human development on pollution emissions which are composite of education, health, and income growth indicators. The testing of the isolated role of education is scant in global literature and absent in Saudi literature. So, this present research is trying to fill this gap.

3. Theoretical framework

The expected inverted U-shaped relationship of income growth and pollutants' emissions, which is known as the EKC hypothesis, is initiated by Grossman and Krueger (1991). It is hypothesized because economic growth requires intense energy consumption during the first stage of development to serve the increasing economic activities which are called scale effects which may be responsible for pollution emissions. Afterward, a clean

environment may also be desired at the second stage of development which may by adopting clean technologies or diversify the economy from dirty industry to clean industry which is termed as technique and composition effects. Here, energy consumption plays an important role in shaping the EKC. Although the main idea of EKC advocates an inverted U-shaped relationship between economic growth and CO_2 emissions, some recent studies argue on a different point of view (Mahmood et al. 2019).

Yang et al. (2015) argued in their study that there is no universal model here that can fit all economies in the world. Other than an inverted U-shape, inverted-N and M shapes may be found in the relationship between income and pollutants' emissions. These results can vary depending on the economic development of a country and how it varies based on the part of the world the country falls in. Li et al. (2019) argued that there is an inconsistency in the nexus between economic growth and CO_2 emissions and mentioned that this relationship has an evolutionary nature that can be affected by time, geography, and socioeconomic aspects of a country. Other than an inverted U-shaped curve, both inverted N and M-shaped relationship can vary in different periods. Alkhateeb and Mahmood (2019) found the positive effect of trade openness on energy consumption. Moutinho et al. (2017) tested the existence of EKC in Portuguese and Spanish economies and provided evidence of an inverted N-shaped EKC. It was narrated that promoting renewable energy in the economies can help to meet urgent goals while the benefits can go a long way. The relationship of the environment and income was tested in six nuclear-generating countries and it was mentioned that nuclear energy has proven to be beneficial for the environment while income can be favorable for the environment in some instances. Nevertheless, both income and CO_2 emissions are determined on a simultaneous basis (Baek and Pride 2014).

Education may play a significant role in tracing the EKC because educated people's preference over clean energy consumption is different from un-educated people. Therefore, education is also a very important variable to regress in any pollution model which is ignored in most of the past literature. From the perspective of economics, education is considered to be a major investment in enhancing the social structure of a community. Its results might not show up immediately since it takes a couple of years for a generation to get educated. However, the long-term results of education cannot be ignored as it delivers more awareness in society and improves social responsibility (Jankal and Jankalove, 2017).

United Nations General Assembly (UNGA) adopted the 2030 Agenda according to which, sustainable development would be planned for the nations, and the agenda was called "Transforming Our World: The 2030 Agenda for Sustainable Development". The purpose of the 17 goals provided under the agenda is to ensure that three major dimensions are integrated including economic, social, and environmental segments. For education, the agenda is to ensure primary education and enable learners to acquire knowledge and skills that can help them to achieve sustainable growth and the agenda is to be achieved by 2030 (UNESCO, 2015). Education is responsible for spreading awareness and can help ensure long-term and sustainable growth (Ergen and Ergen, 2011). With primary education, misconceptions and prejudice can be removed from the societies and social responsibility can improve in communities (Jankal and Jankalove, 2017).

Recent literature has also discussed the role of education in determining energy consumption (World Bank, 2019). Some stream of recent literature also investigates the direct role of education in the pollution emissions and ecological footprints (Balaguer and Cantavella, 2018; Zafar et al., 2019; Ma et al., 2019; Bano et al., 2018). Balaguer and Cantavella (2018) argued that education may contribute to pollution emissions as educated people tend to have better income levels and demand more energy consumption items. On the other hand, education can boost social awareness which may demand clean technologies to reduce pollution emissions. Zafar et al. (2019) argued that human capital helps improve energy efficiency, adopt pollution-free technologies, and reducing fossil-fuel energy use. Further, they also found that human capital remained helpful in reducing ecological footprints in

the United States. Besides, Bano et al. (2018) argued that human capital removes pollution without harming economic growth. Moreover, Yao et al. (2019) reported that human capital is found helpful in reducing 15.36% and 17.33% of total energy consumption and dirty energy consumption respectively in the OECD countries. Further, human capital is found useful in raising 85.54% of clean energy consumption. So, education level and human capital help reduce pollution emissions and shape the EKC as these are promoting clean energy.

4. Methods

Following the theory of EKC, we are hypothesizing the quadratic effects of economic growth on CO_2 emissions. Further, literature also signifies that education and human capital are very important in determining the environmental behavior of educated people in the country. Most of the recent studies on the topic used the human capital or human development indices that capture the education, health, and income indicators (Zafar et al., 2019). But, our objective is to isolate the role of education on CO_2 emissions. Balaguer and Cantavella (2018) hypothesized the role of higher education on CO_2 emissions. But, higher education is obtained by a very limited proportion of the population and it provides specialized education, not the basic moral values. On the other hand, most of the population of any country is just benefited by primary and secondary education where basic moral values and ethics are communicated for personality development. This argument is also matched with the UNGA agenda to ensure at least a primary education for sustainable growth (UNESCO, 2015). Therefore, we are hypothesizing the two proxies of education in the CO_2 emissions model i.e. primary and secondary education, and our model is as follows:

$$C_t = f(Y_t, Y_t^2, PE_t, SE_t, EC_t) \tag{1}$$

All variables in equation 1 are in natural logarithm and t presents a maximum available sample period of 1971-2014. C_t is CO_2 emissions metric tons per capita. Y_t is GDP per capita in constant (2010) US dollars which is a proxy of economic growth and Y_t^2 is square of Y_t. EC_t is energy consumption kg of oil equivalent per capita. Data on C_t, Y_t, and EC_t are sourced from World Bank (2019). PE_t and SE_t are primary and secondary school enrolment ratios respectively. Data on PE_t and SE_t are sourced from the Government of Saudi Arabia (2019). All utilized data are available in the appendix.

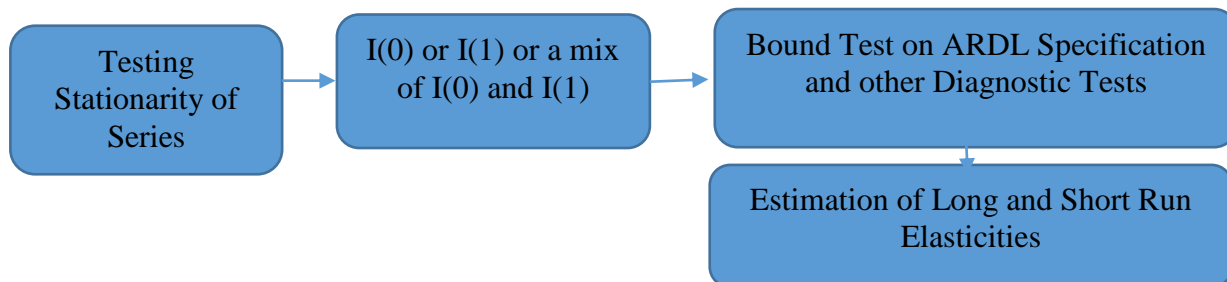
After the model's discussion, a general flow chart is provided in figure 1 to understand the mechanism of estimation. Figure 1 elaborates that we need to test the stationarity of the series at first. In case of level stationary series I(0) or first difference stationary series I(1) or a mix of I(0) and I(1), we may move towards the Auto-Regressive Distributive Lag (ARDL) model because it is efficient in all of the mentioned cases due its bound testing procedure (Pesaran et al., 2001). After validation of cointegration, we may estimate the long and short-run elasticities.


Figure 1. Flow Chart of Estimation

To check the unit root problem in the series, we use Ng and Perron's (2003) methodology because of its superiority and efficiency over the other unit root test due to the de-trending procedure. Moreover, it utilized the four test statistics to confirm the stationarity in the series. After the stationarity test, we may shift our estimation towards the cointegration test. We choose ARDL of Pesaran et al. (2001) which is efficient over other cointegration tests due to its bound testing procedure. Moreover, its parsimonious way of selection of lag lengths also saves the degree of freedom. ARDL model of equation 1 may be expressed as:

$$
\begin{aligned}
\Delta C_t = {} & \alpha_0 + \alpha_1 CO_{t-1} + \alpha_2 Y_{t-1} + \alpha_3 Y_{t-1}^2 + \alpha_4 PE_{t-1} + \alpha_5 SE_{t-1} + \alpha_6 EC_{t-1} \\
& + \sum_{j=1}^{p} \beta_{1j} \Delta C_{t-j} + \sum_{j=0}^{q} \beta_{2j} \Delta Y_{t-j} + \sum_{j=0}^{r} \beta_{3j} \Delta Y_{t-j}^2 + + \sum_{j=1}^{p} \beta_{4j} \Delta PE_{t-j} \\
& + \sum_{j=0}^{q} \beta_{5j} \Delta SE_{t-j} + \sum_{j=0}^{q} \beta_{6j} \Delta EC_{t-j} + \psi_{it}
\end{aligned}
\tag{2}
$$

Equation 2 will be tested for the existence of cointegration on a null hypothesis $\alpha_1 = \alpha_2 = \alpha_3 = \alpha_4 = \alpha_5 = \alpha_6 = 0$ and rejection of which would ensure the cointegration. Afterward, a diagnostic test of heteroscedasticity, serial correlation, normality of error term, and functional would be applied to ensure that estimates are out of econometric problems. Afterward, long-run effects could be calculated from normalizing procedure on the estimated α_i. To capture the short-run elasticities, Error Correction Term (ECT_{t-1}) may be replaced with the $\alpha_1 CO_{t-1} + \alpha_2 Y_{t-1} + \alpha_3 Y_{t-1}^2 + \alpha_4 PE_{t-1} + \alpha_5 SE_{t-1} + \alpha_6 EC_{t-1}$ in the following way:

$$
\begin{aligned}
\Delta C_t = {} & \sum_{j=1}^{p} \delta_{1j} \Delta C_{t-j} + \sum_{j=0}^{q} \delta_{2j} \Delta Y_{t-j} + \sum_{j=0}^{r} \delta_{3j} \Delta Y_{t-j}^2 + \sum_{j=1}^{p} \delta_{4j} \Delta PE_{t-j} \\
& + \sum_{j=0}^{q} \delta_{5j} \Delta SE_{t-j} + \sum_{j=0}^{q} \delta_{6j} \Delta EC_{t-j} + \gamma ECT_{t-1} + \zeta_{it}
\end{aligned}
\tag{3}
$$

In equation 3, negative and significant γ would validate the existence of short-run relationships and speed of convergence and δ_{ij} may explain the short effects in the model.

5. Data Analyses and Discussions

At first, the Ng-Perron unit root test is applied to all series of our model assuming intercept and trend in analysis, and results are reported in table 1. Results show that all series except SE_t are level non-stationary and SE_t is stationary at a 1% level of significance. On their first difference, C_t and Y_t are stationary at 5% and PE_t and EC_t are stationary at a 10% level of significance. Overall, SE_t is level-stationary, and rest all variables are first-difference stationery so mix integration level is substantiated. But, it is sufficient to proceed for the ARDL model as it chooses the lower-bound assuming level-stationery and upper-bound at first differenced-stationary variables (Pesaran et al., 2001). Therefore, the results of ARDL are efficient even in the presence of a mixed order of integration.

Table 1. Unit Root Test

Variable	MZa	MZt	MSB	MPT
C_t	-11.9775(0)	-2.4356	0.2034	7.6703
Y_t	-3.3017(0)	-1.2130	0.3674	26.1391
PE_t	-1.5553(3)	-0.6381	0.4103	37.4287
SE_t	-28.1419(2)***	-3.5849***	0.1274***	4.1856**
EC_t	-2.7809(0)	-1.1282	0.4057	31.1944
ΔC_t	-0.7058(0)**	-3.2054**	0.1548**	4.4746**
ΔY_t	-17.9135(0)**	-2.9801**	0.1673**	5.1414**
ΔPE_t	-14.3397(0)*	-2.6267*	0.1832*	6.6492*
ΔEC_t	-15.3313(0)*	-2.7683*	0.1806*	5.9463*

Note: *,** and *** are showing stationarity at 10%, 5% and 1% level of significance.

ARDL results of equations 2 and 3 are reported in table 2. At first, a bound test is applied to the ARDL equation, and the calculated F-value = 3.6317 is found bigger than critical bound at a 5% level of significance. The critical F-value is used from Kripfganz and Schneider (2018) which is also effective in case of a small sample size like in our case. Hence, a cointegration is corroborated in the model. Further, all diagnostic tests have p-values of more than 0.1 which validate that model has no issue of heteroscedasticity, serial correlation, functional form problem, and normality. Moreover, CUSUM and CUSUMsq tests' values are within critical bound at the bottom of the table, so estimated results are stable.

Table 2. ARDL Results

Variables	Parameter	S.E.	t-value	p-value
Long Run Results				
Y_t	24.9927	10.7700	2.3206	0.0268

In the long run, Y_t has a positive and Y_t^2 has a negative impact on CO_2 emissions. This result is corroborating the existence of EKC in the Kingdom. Moreover, the turning point of the EKC (exponent of 24.9924/2.4652) is found at GDP per capita of 25290 constant US dollar which is more than the average sample period GDP per capita of 22900. Therefore, Saudi Arabia is found in the first stage of EKC, and increasing GDP per capita is responsible for increasing CO_2 emissions. Therefore, economic growth has negative environmental effects by emitting CO_2. This conclusion is matched with the findings of Mahmood et al. (2018) and Mahmood et al. (2019).

In the education and CO_2 emissions relationship, primary education (PE_t) has an insignificant impact on CO_2 emissions. These results make sense because primary education is a very initial stage of human capital and individuals or even groups at this level do not have enough knowledge, understanding, or resources to do something about the environment. Due to the lack of ability of decision making, primary education alone cannot do enough to give someone exposure to the emissions and environmental portfolio of their country. So, primary education is not playing any of its positive or negative role in the environmental profile of Saudi Arabia. This can be due to a reason that education and age of students at the primary level are not mature enough to convey the message of environmental awareness. However, the government should revise the syllabus of primary education to convey the message of a clean environment at this level. Secondary education (SE_t) has a negative and statistically significant effect. It means that increasing secondary education has pleasant environmental effects in terms of reducing CO_2 emissions. Moreover, the elasticity coefficient of *the SE_t* suggests that a 1% increase in SE_t could reduce 0.1223% of CO_2 emissions per capita.

This negative relationship between secondary education and CO_2 emissions corroborates the finding of Balaguer and Cantavella (2018) who found that increasing levels of education would help reduce CO_2 emissions. Further, Zafar et al. (2019) and Bano et al. (2018) also reported negative effects of human capital on the CO_2 emissions and ecological footprint respectively. This leaves a huge room for improvement in the human capital policies in a country since that platform can be used to improve the energy sector to a wide extent. Considering the multi-dimensional nature of the energy sector, it is crucial to understand that not only the policies in the energy sector can make an impact; but any decisions taken in other sectors can have a strong impact on the segment as well. It must be taken into consideration that improving the education sector can go a long way, not only would the nation have a way more educated generation, but the environment would have improved as well which would be a win-win situation for the nation in the long-run. Lastly, energy consumption (EC_t) has a positive impact on CO_2 emissions and a 1% increase in EC_t could increase by 0.182% of CO_2 emissions.

In the short run, the negative and significant γ of ECT_{t-1} corroborates the short-run relationship in the model. Further, the magnitude γ shows that short-run fluctuation could set back at a speed of 45.14% a year on the long-run path. Further, economic growth, its square, and primary education could not affect CO_2 emissions. However,

secondary education has again negative effect on the CO_2 emissions with a relatively higher elasticity coefficient compare to the long-run result. A 1% increase in SE_t could decrease the 1.0402% of CO_2 emissions. Moreover, the energy consumption has a negative short-run effect on the CO_2 emissions and a 1% increase in EC_t may increase the 0.5895% of CO_2 emissions.

Conclusions

Education may play a positive environmental role by reducing pollution emissions if education could enhance the social responsibility of the citizens. This present research tries to test the effects of primary and secondary education on the CO_2 emissions along with testing the conventional determinants of CO_2 emissions. We apply the ARDL cointegration test and use a period of 1971-2014 to investigate the said relationships. We found the cointegration in the hypothesized model and short-run relationships are also found with a speed of convergence, 45.14% a year. We validate the EKC hypothesis in Saudi Arabia with a point of inflection at 25,290 GDP per capita. But, the kingdom is found at the first stage of EKC hence its economic growth is responsible for environmental degradation through emitting CO_2. Further, the short-run effect of economic growth is found insignificant. The effect of primary education is found insignificant but increasing secondary education is found helpful in reducing CO_2 emissions. Moreover, energy consumption is increasing CO_2 emissions. Based on the results, we recommend the Kingdom to promote secondary education in the Kingdom to improve the awareness of the social responsibility of reducing pollution emissions and to use clean energy sources to remove the negative environmental effects of economic growth. Additionally, since it is mentioned that secondary education has an impact on the environment; there should be more efforts to take the educational system of the country up a notch to ensure that the segment provides positive results not only for the human capital but for the environment as well. This multi-disciplinary approach would be creative enough for the nation to move ahead and take serious actions to stop the environmental degradation in the country.

Abstract. The goal of this study is to identify the problems and barriers that impede the growth and development of small and medium innovative enterprises (innovative SMEs) and suggest ways to overcome them. The main methods of the study include a survey of the founders of innovative companies from Russia and Belarus, as well as expert interviews. The study involved both mature companies and startups. The results of the study indicate that most innovative companies lack personnel with the necessary education and experience. At the same time, the number of researchers is decreasing, and external part-timers are being involved to carry out the research. The innovative activities in the countries under study remain low. The main barriers to the growth of this indicator include the lack of financial resources, the difficulties with raising external financing, as well as the shortage of the professional personnel. A set of measures to financially encourage researchers and tax incentives for innovative entrepreneurship are proposed as the main incentives to increasing the innovative activities.

1. Introduction

There has been an increase in investment in innovation worldwide in recent years; the use of intellectual property has reached record levels (The Global Innovation Index 2019). According to Eurostat, R&D expenses increased by 53.5 % in the EU member states, by 65 % in the US, and almost 2.9 times in South Korea for 2009 – 2017 (Eurostat, 2020a).

Most of the global R&D expenses were in the business sector. The share of private sector investment in R&D amounted to 61.2 % of the total R&D expenses in the EU member states, 73 % in the US, 78.8 % in Japan, and 79.4 % in South Korea in 2017.

SMEs have traditionally been recognized as the driving force behind growth and innovation in the economy. For example, the business sector of the EU member states (27) accounts for 66.4 % of the total domestic R&D expenses (Eurostat, 2020b). The European business sector employs 51.3 % of the total R&D personnel (Eurostat, 2020c).

Despite the relatively small R&D budget, a third of the annual patent applications at the European Patent Office are filed by innovative SMEs (Patent Index 2019).

However, the level of innovative activities of SMEs in middle-income countries, including Russia, Kazakhstan, and Belarus, is significantly lower than that in high-income countries. For example, about 72 % of the total number of SMEs are introducing a new product or business process in Sweden, 71 % in Norway, 67 % in Belgium, 64 % in the US, and 62 % in Germany. This indicator is about 5 % in the Russian Federation (OECD, 2020), 7.2 % in Kazakhstan (On the innovative activities of enterprises in the Republic of Kazakhstan, 2018), and 4.3 % in the Republic of Belarus (National Statistical Committee of the Republic of Belarus, 2018).

Small businesses trying to market the innovative technology products and services often face unique problems and barriers that large multinational corporations do not face, and they often need to overcome such barriers with fewer resources (Bushueva, et. al. 2020). The shortage of human resources is a particular problem for SMEs, because the number of specialists who are knowledge holders and have the necessary competencies and experience in innovations is extremely limited (Dudin et al. 2020).

Encouraging employment in the innovative sector and encouraging youth to start their own businesses and to create breakthrough technology become important measures to expand the innovative activities of SMEs (Muraya, et. al. 2019). Significant potential for attracting personnel to innovative areas lies in the development of new forms of employment. For example, such forms of employment as freelancing, self-employment with hired workers, etc. are becoming more common in European countries (Danilina, et. al. 2020)

The problems faced by individual entrepreneurs and fast-growing SMEs when trying to commercialize an innovative product or service have been examined in this study.

The hypothesis has been formulated during the study that the encouragement of the forms of self-employment and the creation of new SMEs in research and innovation are flexible tools for the growth of innovative activities and are vital for the economic growth of countries with developing economies.

2. Literature review

Innovations represent the introduction of a new or significantly improved product (goods or services), a process, a new marketing method, or a new organizational method in business practice, workplace organization, or external relations (Mohd Rosli & Syamsuriana Sidek 2013).

Many studies confirm the positive impact of innovation on business performance (Galindo & Méndez-Picazo 2013; Saiz-Álvarez, et. al. 2013; Lucchese & Pianta 2012; Wang et al. 2019; Kumar, 2019; Laužikas, Miliūtė, 2020).

It is important to note that new products and services must be commercialized, i.e., marketed in order to be considered innovations (Klyver, et. al. 2012). Innovative entrepreneurship is one of the main means by which new knowledge and technology are transformed into economic and social benefits (Baumol 2010).

A significant share of the works in the contemporary scientific literature is devoted to studying the degree of influence of innovative entrepreneurship on the socioeconomic development of a country (De la Hoz-Rosales, et. al. 2019; Acs, et. al. 2012; Aparicio, et. al. 2016; Karshalova, et. al. 2017), the factors that determine innovative behavior and the offer of new products by SMEs (Velilla & Ortega 2020; Castaño, et. al. 2015), and the innovative entrepreneurial education (Lee, et. al. 2020; Chen, et. al. 2018).

Financing problems (Li, et. al. 2015; Giraudo, et. al. 2019; Bertoni, et. al. 2019; Colombo, et. al. 2013; Giudicic, et. al. 2018), patent protection issues and incentives for investment in innovative startups (Cumming, et. al. 2017; Grilli, et. al. 2018), and government support measures (Ruchkina, et. al. 2017; Mas-Tur & Simón 2015; Grilli, et. al. 2018) for young innovative companies are some of the relevant areas of research.

The development of innovative entrepreneurship and the digital transformation of the society have led to the emergence of new forms of work that are significantly different from standard labor relations. Certain aspects of the development of new employment forms in SMEs are reviewed in the works of Orlova (2017), Kirchhoff (2007), Serrano (2010), Alois (2020), and others.

The studies indicate that the forms of employment based on open and temporary contracts, freelancers, and self-employment with hired workers are gaining popularity in the world now (Eurofound, 2018).

The study of the scientific literature reveals that there have been relatively few empirical data around the world until recently to answer the question about the participation of SMEs and self-employed workers in the development of an innovative economy. The early studies relied on data from officially registered companies, leaving informal forms of employment, which in many countries were the largest source of employment, out of the picture.

As such, the problems of entrepreneurship development and self-employment in innovative sectors of the economy remain poorly explored.

3. Methods

The trends based on the opinions and intentions of the population and the heads of SMEs, describing the dynamics and scale of innovative processes, factors constraining innovative activities, and barriers to the development of innovative entrepreneurship have been revealed in the course of a specially organized market observation.

The key questions addressed in this study are the following: how innovative are SMEs in various sectors and by international standards? Why and when do SMEs invest in research and innovation? Where are the barriers and potential for research and innovation?

A methodology was developed to accomplish these tasks, which included the collection and analysis of primary qualitative and quantitative data. A random sample was made for the survey to ensure that the opinions expressed during the survey were representative.

The goals of sampling included maximizing the number of responses and ensuring the representativeness of the population and SME enterprises. The survey was conducted online.

The experts were selected based on the professional status of a person. They included people whose professional activities were related to the relationship between the institute of entrepreneurship for more than two years. The sample included two groups of respondents: 516 respondents from the population of three countries in the post-Soviet space (Kazakhstan, Russia, and Belarus) and 244 SMEs engaged in innovative activities.

During the study, the SMEs were asked to evaluate their satisfaction with various aspects of their development. The evaluations had to be given on a 10-point scale, where 1 meant absolute dissatisfaction, 10 meant absolute satisfaction, and 0 meant that this indicator was not significant for the company development or difficult to evaluate.

In addition, the respondents could choose multiple answers for some questions. The substantiated answers were obtained from the generalized comments of the respondents.

All participants were warned about the purpose of the survey and that the study organizers were planning to publish the generalized results of the study in the future. All expert quotes were provided in the article anonymously. The experts chose the language they answered the question (Russian or English) themselves.

4. Results

The average age of the SMEs participating in the survey is 2.5 years. The main share is made up of the companies created less than one year ago (Figure 1).
Figure 1. Age structure of the SMEs participating in the survey, % of the total number of respondents

The largest share of the enterprises surveyed (52.7 %) are research organizations and higher education organizations (22.3 % of the respondents). The companies surveyed in the three countries do not have significant differences, depending on the type of business (Figure 2).
Figure 2. Structure of the innovative SMEs, % of the total number of respondents

The areas of activity of the SMEs participating in the survey are quite diverse. For example, almost half of the experts surveyed represent the telecommunications, media, and technology sector (Figure 3). About 22.8 % of the surveyed companies work in the biotechnology and pharmaceutical sectors, 16.1 % of the companies participating in the survey create technological solutions for specific industries, 10.3 % create innovations in instrument engineering, and the remaining 4 % of the innovative companies specialize on the developments for the consumer sector and education.
Figure 3. Structure of the respondents by field of activities, %

The vast majority of the companies participating in the survey are mature. At the same time, 10.7 % of the experts noted that their company was at the stage of the stable product monetization. Most of the companies surveyed are in the business scaling stage, i.e., according to experts, their enterprise is able to cope with an increase in the volume of work or output in a cost-effective and reasonable way at the current stage of development (Figure 4).

The share of mature innovative enterprises is at approximately the same level and amounts to 22.3 % in Russia and 21 % in Kazakhstan. This indicator is slightly lower in Belarus and amounts to 16.9 % of the total number of innovative companies.
Figure 4. Structure of the respondents by the stage of development of innovative activities, % of the respondents

About 17 % of the companies surveyed are currently at the startup stage and have no revenue, while the annual revenue of 27 % of the companies is less than USD 15,000. The distribution of respondents by average annual revenue is provided in Figure 5.
Figure 5. Distribution of the respondents by annual revenue for the previous year, % of the respondents

The experts were asked to evaluate the degree of their innovations during the study. For example, the majority (43.3 %) of the companies say that their product is an improvement in innovation. More than a third of the companies surveyed (37.9 %) describe their products as having advantages and disadvantages over peers, but not being significantly better. Radical innovations are created by 17 % of the companies that offer fundamentally new solutions and provide a technological breakthrough. The distribution of the expert opinions on the level of innovation of their products or services is presented in Figure 6.
Figure 6. Distribution of the expert opinions on the level of innovation of their products or services

The managers of almost 62 % of the surveyed SMEs indicated an increase in internal spending on R&D over the previous three years (Figure 7).
Figure 7. Evaluation of internal spending on R&D, % of the respondents

The total number of the personnel in the surveyed organizations was 5,824 people. As such, the average number of employees in innovative SMEs is 26 people.

The results of the study indicate that the companies with up to five full-time employees dominate in the innovative sector today, their largest part being from Russia. Most of the innovative companies from Kazakhstan and Belarus participating in the study have full-time personnel of six to 20 people. Almost every fourth company employs from 21 to 50 people. The distribution of the innovative companies among the three countries by the number of personnel is presented in Figure 8.
Figure 8. Structure of innovative enterprises by the number of personnel

About 90 % of the respondents say that about half of the personnel in their organizations are researchers. At the same time, 178 respondents (79.8 % of the respondents) noted that the number of researchers had decreased over the previous three years, 16.5 % of the experts said that the number of researchers remained the same, and only 3.7 % noted an increase in this indicator. At the same time, similar trends in the decrease in the number of researchers employed by innovative enterprises are observed in Russia, Belarus, and Kazakhstan.

The widespread part-time format is an interesting feature of the labor market in the innovative sector. Almost half of the experts (48.7 %) from the SME managers note that they involve external part-timers and researchers under civil law contracts to carry out the research work.

The structure of employment of part-timers in innovative companies in Russia, Belarus, and Kazakhstan is similar: the majority of part-timers work in science and education and in the high-tech industry (Figure 9).
Figure 9. Employment structure of part-timers in innovative companies, % of the respondents

About 58 % of the experts noted that self-employed workers (freelancers) were involved in the development of individual topics, projects, as well as for the performance of certain works or provision of certain services.

One expert from the high-tech industry noted that R&D freelancers were involved in research that did not require experiments at scientific laboratories and the use of sophisticated equipment.

According to the expert, it is easier and cheaper to find a qualified freelancer for a one-time project than to adapt a new employee today.

The managers of more than 40 % of the companies noted that independent experts were involved in the implementation of individual projects. The most popular freelance professions involved in innovative projects are "web and mobile design", "development of other software", "development of desktop software", "e-commerce development", "product management", and "Q&A testing".

It must be noted that, despite the possibility of hiring part-timers in the innovative sector, more than half of the innovative companies (51.8 %) lack staff with the necessary education and experience.

The companies feel the particularly acute lack of specialists in the following activities: promotion, sales, and PR were indicated by 58.6 % of the innovative companies experiencing staff shortages; research and analytics (52.6 %); information technology (45.7 %); and strategic management (44 %).

At the same time, staff shortages are not a critical problem for the research participants in the development of their activities. The experts name a shortage of financial resources, difficulties in raising external financing, as well as a shortage of professional personnel as the main obstacles to the growth of the innovative activities of the population and SMEs (Figure 10).
Figure 10. Barriers to increase innovative activities, % of the respondents

The analysis of expert opinions indicates that the relevance of barriers depends on the stage of development of an innovative product and/or technology.

For example, the main problems at the startup stage are the lack of funding and the difficulties of translating the idea into a product and the difficulty of obtaining external financing. More mature enterprises are more likely to experience difficulties associated with business growth, staff shortages, and the organization of internal processes.

5. Discussion

The results of the study reveal that many aspects of the development of innovative ecosystems in Russia, Belarus, and Kazakhstan are quite similar and generally do not correspond to the scientific and technological potential. The development of innovative SMEs in the three countries has common problems: the limited access to financing, the low motivation for innovative activities, and the lack of personnel with the necessary level of education and experience. This is generally consistent with the results of studies on entrepreneurship issues (Biryukov, et. al. 2020; Suglobov, et.al. 2020; Dudin et al. 2020; Krasnov, et. al. 2019). However, attention should be paid to some important issues.

The vast majority of the experts (89.7 %) expressed the view that the development of innovative entrepreneurship depended on the efficient measures aimed at encouraging the inventive activities of the population and at creating favorable conditions to reduce the shortage of professional and experienced personnel in innovative companies.

Three quarters of the experts agree that financial support measures for inventors and tax incentives are the main incentives for innovative activities (Figure 11).
Figure 11. Incentives for innovative activities of the population, %

The experts name the need for legislative consolidation of the responsibility of employers for the late payment of remuneration to the inventors, as well as establishing minimum amounts for paying for the creation of intellectual property results as the priority measures aimed at enhancing the financial motivation of inventors (Figure 12).
Figure 12. Priority measures to enhance the financial motivation of inventors

The rules for the payment of remuneration to the authors of employee inventions, utility models, and industrial designs are currently established at the legislative level in the countries under study. However, the need to conclude special agreements and the lack of responsibility for nonpayment of such remuneration established at the legislative level discourage employees of universities, research institutes, and innovative companies.

In the course of the interview, the experts proposed introducing standards into national laws providing for the procedure for paying remuneration for the creation of intellectual property results and the commercialization of inventions, models, and industrial designs.

About half of the experts (48.7 %) consider it necessary to consolidate the responsibility of employers for the late payment of remuneration to the inventors at the legislative level, and 43.3 % of the respondents spoke in favor of setting the minimum amount of payments for creating the intellectual activity results. About 39.3 % of the respondents note the possibility of establishing the minimum amount of remuneration to the author or the team of authors in the event of the conclusion of a licensing agreement between the employer and the third party for the right to use an employee invention.

A third of the experts surveyed (33 %) noted the need for a mechanism to offset the costs of "commercial packaging" of the invention.

The mechanism of an innovative voucher can solve this problem. The experts proposed to study the innovate experience of the EU member states and to prepare the necessary regulatory framework in order to launch the mechanism for using innovative vouchers. Innovative vouchers provide firms with a financial incentive on a noncompetitive basis (as opposed to cooperative R&D grants) to introduce small-scale innovations by establishing links between the SMEs and the state research institutions. They serve the dual purpose of directly encouraging the exchange of knowledge and of building long-term relationships between the industry and the knowledge providers. Voucher schemes provide small amounts of the state subsidies to the SMEs to help them access external support to develop specific competencies. An analysis of international experience in applying voucher schemes suggests that they can help SMEs increase their innovative potential and overcome specific barriers to their development, such as risk aversion.

Slightly less than a third of the experts (31.8 %) note that there are no mechanisms allowing inventors to participate in exhibition and forum events abroad on favorable terms today. They offer to extend the mechanism of cost compensation for the participation in such events as measures of financial motivation.

About 27.7 % of the experts believe that the rules for compensation for the costs for patenting abroad in force in the countries under consideration do not apply to individuals. They noted the need to include these rules in the program to support the export of intellectual property rights.

Almost a quarter of the experts (24.1 %) propose creating a mechanism similar to the deposit insurance system, which will allow banks to lend against intellectual property while insuring the risks in insurance companies.

Tax incentives were mentioned by 72.3 % of the experts as a motivation for the development of innovative entrepreneurship. The experts propose the abolition of VAT, the introduction of a multiplier for the costs of patent services, tax exemptions for transactions with intellectual property rights, and the payment of compensation through taxation of the expenses for patenting abroad as the main tax incentives (Figure 13).
Figure 13. Tax incentive measures, % of the respondents

The existing VAT collection schemes in Russia, Belarus, and Kazakhstan create a barrier between the innovative SMEs and the large companies that require "input" VAT. The experts (24.6 %) made a proposal to replace VAT on products manufactured in the countries under study with sales tax. This will allow to transfer the tax burden to the retailer without budgetary losses as the final link in the production and sale chain.

Due to the postponed economic effect of inventive activities, there are currently no patent services in the structure of many companies. About 18.8 % of the respondents suggested that the costs associated with the maintenance of patent offices should be attributed to the production costs for income tax purposes.

More than 16 % of the experts identified exemption from taxation on the transactions related to the payment of author's royalties, sale of rights under license agreements, and sale of exclusive rights to inventions as incentive measures.

The experts indicated infrastructure support for intellectual property (43.3 %), the development of new forms of integration of universities and industrial enterprises (39.3 %), customs protection of domestic copyright holders (36.2 %), and improving the technology transfer system (33.9 %) almost twice less often than the financial support for authors and tax incentives.

As such, it can be stated with great confidence that the application of the above incentive measures in combination with the efficient mechanisms for creating a market for new inventions will create favorable conditions for the development of entrepreneurship and forms of self-employment in innovative sectors of the economy.

Conclusion

The results obtained in the course of this study have confirmed the hypothesis and are an important step towards the formation of a comprehensive identification of the existing innovative landscape in the three countries of the EAEU integration association and the development of directions for its development.

Despite the available innovative potential, the level of innovative activities remains quite modest. The main barriers to the development of innovative entrepreneurship are the lack of financial resources, the unforeseen expenses, processes, etc., and difficulties in raising the external financing.

The main measures to encourage the innovative activities of the population in the EAEU member states include financial incentives for inventors, tax incentives, infrastructural support for intellectual property results, development of new forms of integration of universities and enterprises, customs protection of domestic copyright holders, and improvement of technology transfer systems.

Abstract. As per newspapers and national news reports, small and medium-sized enterprises (SMEs) in Indonesia, currently 26,574 in number, are spreading widely. The transformation of SMEs to large, mature business entities is slow. This study investigates the sluggish transformation of SMEs in Indonesia and offers new explanations for the sluggishness, focusing on knowledge empowerment instead of financial aspects. A new development model was constructed with an aim to enhance SMEs. This study serves as research with a paradigm of constructivism, prioritizing knowledge empowerment. Executive officers of SMEs should aim for the construction of conceptual knowledge of social networks and social cognition in a sequential-ordered logic to achieve organizational readiness and readiness for change. They, moreover, internalize these concepts to transform SMEs into large, mature business entities with high levels of competitiveness, leadership engagement, dynamic capabilities, and profound sustainabilities.

Keywords: networking; social networks; social-cognitive; readiness for change; innovativeness; optimism; commitment; efficacy

1. Introduction

First, this study investigates the sluggish transformation of SMEs in Indonesia, caused by Indonesian regulators' concentration on financial capabilities for SMEs. However, researchers argue that the sluggishness is due to a lack of knowledge empowerment. This study develops a model to explain how SMEs can efficiently transform using conceptual knowledge of social networks, social cognitive, organizational readiness, and change. To support the research model that could be used to deter the sluggishness, this research posits social network (Fatoki, 2011; Jones & Volpe, 2011; Lee et al., 2010; Zhou et al., 2007; Galaso, & Kovářík, 2018; Belz et al., 2019), social cognitive (Bandura, 1986, 1988, 1989, 2008), organizational readiness (Chen et al., 2019; Coleman et al., 2019; Dabholkar, 1996; Islam et al., 2019; Puklavec et al., 2014), and readiness for change (Heckmann et al., 2016; Weiner et al., 2008, 2009; Kuzmin, & Barbakov, 2015). All theories are constructed by this study into a sequentially ordered research model and conclude in organizational readiness for change.

This research offers a fresh perspective in several ways. First, it can explain the construction of the transformation of SMEs to achieve organizational readiness and change. The capability of SMEs to form social networks (Chen et al., 2019; Fatoki, 2011; Jones & Volpe, 2011; Lee et al., 2010; Zhou et al., 2007) and their social cognition (Bandura, 1986, 1988, 1989, 2008; Boudreaux et al., 2019; Majid et al., 2017) supports the development of SMEs in terms of organizational readiness and change. SMEs could achieve growth opportunities by expanding their network and capture social cognitive phenomena. Researchers argue that these SMEs could be sustainable because of their social capital. The social capital of SMEs is rooted in supply chain networks, which can reduce inter-dependencies on an individual supplier. Moreover, SME's social capital has the shape of cumulative knowledge, which is used to counter environmental uncertainties and pressures. In other words, SMEs have self-efficacies that are equivalent to knowledge capital to solve future problems.

Second, this research focuses on the constructivism paradigm, which emphasizes knowledge empowerment for owners and executive officers of SMEs rather than the financial aspect. The enhancement of Indonesian SMEs did not merely need financial capital, but also inducements of social network and social cognitive knowledge that could save them in the future. This study argues that knowledge supremacy is a strategic transformation process to empower SMEs. In the negation statement, this research disagrees with the concept of SME enhancement, which is centered on financial capital. The researchers argue that the tactical method for SME transformation is to use knowledge empowerment as a supreme strategy. We also suggest that knowledge empowerment is closed to technocracy, agreeing with Mcdonnell & Valbruzzi (2014) and Obar (2016).

Third, this study develops a new model to achieve organizational readiness and change for SMEs to enable them for high growth opportunities, competitiveness, and dynamic capabilities, as suggested by extant research. This research model developed new constructs—social network and social cognitive—to prepare SMEs for organizational readiness and change. Previous studies employed the constructs of business, financial, and innovator characteristics (Chelliah et al., 2010; Durrah et al., 2016; K. Li et al., 2016; Majocchi et al., 2015; Noori et al., 2017; Tongli et al., 2019) to explain the readiness of SMEs. The researchers arranged all constructs in ordered-sequential associations with nomological validity, ascertaining ordered-sequential structures for the new model. These associations were recommended by Kraus & Tan (2015) and Hamid et al. (2015) in relational constructivism.

This study used the assumption that SME owners and executive officers primarily run their business by considering costs and benefits and thus have beliefs, attitudes, and behaviors with high self-control (Timpano & Schmidt, 2013; Willems et al., 2018). The second assumption is that this study ignores the events of state-directed agenda to empower SMEs in all aspects of the Indonesian local government. This research could not take into account regional government agendas due to 34 Indonesian provinces that had governors. Therefore, it is ceteris paribus that provincial programs for SME empowerment are excluded from the discussion.

This study makes contributions to regulators of Indonesia's government consciousness to empower and control SME growth and transformation. The consciousness should be grounded in prioritizing knowledge empowerment in addition to financial capitals, which can enhance the abilities and capabilities of SMEs to transform themselves (Mcdonnell & Valbruzzi, 2014; Obar, 2016). Regulators should enhance cumulative knowledge for SME owners and executive officers, especially in social networks and social cognition, as these constructs could improve organizational readiness and change for SMEs. On the other hand, the Indonesian government should place the highest priority on knowledge dissemination to increase the dynamic capabilities of SMEs in the future (Fatoki, 2011; Jones & Volpe, 2011; Lee et al., 2010). The Indonesian government must disseminate information on social networks and social cognition to SME owners and executive officers to improve their organizational capabilities and provide them with growth opportunities, competitiveness, and robustness from environmental uncertainties.

This study specifies the core skills and competencies that SME owners and officers should be made aware of the needs. Skills and competencies derived from social networks are networking abilities. The acquisition of networking abilities could transform SMEs to enterprising their organization, thus reducing the firm's risk (Fatoki, 2011; Lee et al., 2010). On the other hand, skills and competencies derived from social cognition are forethought, self-reactiveness, self-reflectiveness, and proactiveness (Bandura, 1986, 1988, 1989, 2008). Acquisition traits of competencies derived from social cognition could enable SME owners and officers to be flexible and dynamic when facing future environmental uncertainties. The traits derived from social networks and social cognition could enhance the transformation of SMEs with organizational readiness and change.

From the first and second contributions, this study refers to economic and political consequences Commerford et al., 2018; Koenig & Eagly, 2014) for which the Indonesian government must formulate policies to enhance organizational readiness and change (Heckmann et al., 2016; Lizar et al., 2015). The first policy should relate to the inter-sharing and communication of knowledge among SMEs in other industrial types and provinces to improve the social network of SMEs (Ali et al., 2019; Chen et al., 2019; Mehreen et al., 2019; Yamin & Kurt, 2018) and their social cognition (Arraya & Porfírio, 2017; Riley et al., 2016), especially in networking abilities around Indonesia. Moreover, this policy could create a potential demand for SME products and services with market shares across all areas of Indonesia. Meanwhile, inter-knowledge sharing and communication could educate and train SME owners and officers on how to internalize social cognition (H. Li et al., 2015; Pacillo, 2016) so that they may improve their foresight.

Section 2 presents the theoretical background, specifically, the motivation behind the intention of SMEs to conduct social networks, social cognitive, organizational readiness, and change. Section 3 presents research designs along with data collection and statistical tests for the reliability and validity of the models. Chapter 4 discusses the statistical results. This section also discusses the logic of statistical results and research findings and their inferences. Part 5 discloses conclusions, limitations, and designs for future research.

2. Theoretical Backgrounds and Hypotheses Development

Social Network Theory and Networking
Social network theory (SNT) explains an individual's or organization's need to construct relationships with those who have resources (Chen et al., 2019; Mehreen et al., 2019; Yamin & Kurt, 2018; Zhou et al., 2007). This connection usually has the motivation to maintain individuals' continuance to live in their environment. Meanwhile, business organizations make numerous connections to reduce dependencies on suppliers and improve future sustainabilities. This study infers that individuals or organizations consider the social network through networking to increase social capital (Leask & Parker, 2006; Liu et al., 2017). With the primary motivation of increasing knowledge, most SMEs conduct networking with knowledge dissemination internally and externally with others.

Organizations are generally keen to increase collaboration, which is used to create their innovation potentially (Leask & Parker, 2006) to gain benefits from connections with other firms. The most significant advantage is innovation (Ali et al., 2019; Chen et al., 2019; Fatoki, 2011; Yamin & Kurt, 2018). Researchers argue that SMEs could increase their relationships with others to make sustainable improvements (Rajala & Westerlund, 2010), alternative resource choices (Leask & Parker, 2006), and a repository of problem-solving techniques (Applegate et al., 2006; Bjelland & Wood, 2008). This study, therefore, infers that SME owners or executive officers have invisible colleges (Crane, 1972) as they conduct networking. The SMEs could thus help such firms solve business problems, run operating activities, and achieve their missions with others.

This study associates SMEs conducting social networks and organizational readiness because SMEs have active networking; they are organizations with abilities, capabilities, and the power to solve business problems, efficiently run operating activities and profoundly achieve missions and goals. These SMEs are highlighted as firms whose dynamic capability is high, business capacities are transformable, and competitiveness level is high. This research, therefore, concluded that SMEs have high organizational readiness and need for change, as they could be transformed (Applegate et al., 2006; Philip & McKeown, 2004; Yamin & Kurt, 2018). Moreover, these SMEs are firms where owners and executive officers have appropriate cumulative knowledge.

Social-Cognitive Theory
The social cognitive theory (SCT) states that individuals study and learn social phenomena to collect knowledge from societies. People tend to seek additional knowledge to justify their abilities and capabilities and use these to improve their lives and maintain sustainability. These individuals thus practice the SCT (Bandura, 1986, 2008; Boudreaux et al., 2019; Oo et al., 2018; Wang et al., 2019). This study likens human behavior with SCT from the perspective of organizations like SMEs that accumulate knowledge as they seek new business opportunities to conglomerate the firm's activities. Consequently, these SMEs maintain their operations and improve their operational, marketing, financial, and administrative powers.

The SCT argues that learning is crucial to acquire skills, methods, and strategies for a better life. Through learning, individuals and organizations identify and strengthen their beliefs (Bandura, 1988, 1989; Boudreaux et al., 2019; Wang et al., 2019). This study proposes that organizations may enhance their self-efficacy due to highly acquisitive pieces of knowledge. Furthermore, these organizations are expected to outdo other firms in terms of business. In other words, SMEs could improve their self-efficacy by learning how other firms conduct their business. In the identification perspective, SMEs learn social phenomena and use opportunities to develop new procedures, methods, and business.

This study proposes that the capabilities of SMEs employ social cognition to develop organizational readiness and enable change. Thus is supported by the argument that SMEs acquire motivation because they have new expectations for future business due to self-efficacy. This study agrees with Bandura (2008) that SMEs acquiring social cognition would have self-reflective, self-regulation, and vicarious capabilities. These SMEs, therefore, could adopt skills and knowledge that develop cognition and affection to change future directions. Researchers argue that the acquisition of social cognition is useful to SMEs as it supports the business transformation process. The conclusion affirms that such SMEs could transform with their capacities of organizational readiness and readiness for change significantly.

Business Characteristics

This study discusses business characteristics from three perspectives—firms, finances, and innovators. It associates these business characteristics with the performance of SMEs, which are measured with organizational readiness and capacity for change Tongli et al. (2019), Durrah et al. (2016), and Noori et al. (2017) suggested that business characteristics play a determinate role in SMEs' financial and non-financial performance. Researchers argue that the type of firm, financial situation, and innovator's knowledge are resources that could be used by SME management to generalize profits in their business. This study proposes that organizational readiness and capacity for change for SMEs are developed by these characteristics, as suggested by extant research concerning business performance.

The first type is the firm characteristic that measures SME profitability, firm-size, market share, social responsibility, and economic value (Chelliah et al., 2010; Noori et al., 2017; Wincent, 2005). The second type is the financial characteristic, including liquidity, solvability, financing method, turnovers of inventory, receivable, and cash, and default probability (Li et al., 2015; Li et al., 2016; Majocchi et al., 2015). The third type is innovator characteristic arising from future potential benefit, strength, opportunity, weakness, threats, skill, expertise, and environmental fit, which are imbibed in SME cognition of its owners and executive officers (Cant et al., 2014; Chittithaworn et al., 2011). Researchers took into account these three types of characteristics that extant studies have handled mainly as indicators of business performance (Durrah et al., 2016; Noori et al., 2017; Tongli et al., 2019).

This study argues critical reasoning of the association between business characteristics and their organizational readiness and adaptability for change. It believes that the bundling of the firm, financial, and innovator knowledge are a combination of tangible and intangible assets used to generate future cash inflows. These characteristics are also used to enable SME management to be more significant and ready for change (Coleman et al., 2019; Puklavec et al., 2014, 2018). SMEs thus benefit from the existence of these characteristics to capture future potential business by acting on their forward-looking capabilities. This study concludes that such SMEs are those that have the organizational readiness and readiness for change because they have anticipated future environmental pressures and uncertainties.

Organizational Readiness
A person's readiness is highlighted by the positive-additional motivation to lead missions, goals, and direction (Coleman et al., 2019; Liljander et al., 2006; Pruitt, 2015; Puklavec et al., 2018). An organization or person uses the motivation to achieve missions, goals, and directions as a resource to solve organizational problems and control all activities aligned with management requirements. Using motivation, researchers propose that SMEs can create behavioral optimism that supports individuals and organizations with dynamical skills and abilities (Liljander et al., 2006; Loyd & Gressard, 1984; Munger & Loyd, 1989; Scheier & Carver, 1987). Studies have also suggested that individuals or organizations that utilize their optimism are also highly creative (Puklavec et al., 2018). It has been found that SMEs with organizational optimism is highly sustainable and can achieve their organizational mission and goals due to this optimistic commitment (Coleman et al., 2019; Puklavec et al., 2018). On the other hand, an organization's creativity has consequences on its innovativeness (Chen et al., 2019; Coleman et al., 2019; Norman, 1999; Pratibha Dabholkar, 1996; Walker et al., 2016). This study thus concludes that SMEs with innovativeness have the organizational skills and readiness to transform into a higher business class.

SMEs that intend to expand their business should thus have the qualities of optimism as well as innovativeness (Chen et al., 2019; Coleman et al., 2019). With these qualities, SMEs are ready to be transformed using the intangible capital of knowledge. An SME's resources in intangible capitals are used by owners or executive officers to shift business at the industrial level or for conglomerate enlargement. Finally, this study evinces that knowledge is a tool for SMEs to prepare for higher organizational readiness and concludes that whether

organizational readiness is achieved or not depends on whether the management of these SMEs considered knowledge as primarily important.

Organizational Readiness for Change

Organizational readiness for change refers to the transformational capacity of an entity for enhanced levels of operation or scalability (Heckmann et al., 2016; Lizar et al., 2015). Researchers argue that SMEs may or may not be transformed. The organizationally cumulative knowledge, as well as owners' and executive officers' capacities, support the contingency of the transformation process. According to Heckmann et al. (2016), Lizar et al. (2015), Weiner (2009), Weiner et al. (2008), the transformation process for a business organization depends on the "change commitment" and "change efficacy." Therefore, we argue that SME owners and executive officers who have cumulative knowledge support the process of "change commitment" and "change efficacy" development. This study proposes that organizational readiness for change depends on whether the SMEs possessed "change commitment" and "change efficacy." In other words, "change commitment" and "change efficacy" function as intangible assets for the SME. This intangible asset, therefore, is used to transform the business of SMEs to become more significant dynamic capabilities.

3. Hypotheses Developments

Researchers argue that the networking abilities of SME owners could improve their organizational performance. Thus, as innovators, SME owners perpetually seek new relationships in supply chains and customers. SME owners and executive officers expand their connections to diminish dependencies on limited resources by practicing social network concepts with learning and communication. Due to an expansion in their connectivities, SMEs can prepare for organizational readiness and can easily transform into higher capacities. Therefore, the following hypotheses H1a and b were formulated.

H1a: Social networks positively influence organizational readiness for SMEs.
H1b: Social networks positively influence organizational readiness for change for SMEs.

Similar to the logical reasoning of hypotheses H1a and b, this research argues that SMEs' abilities to capture and internalize social cognition would make them precautious, self-reflective, self-reactive, and proactive. If owners or executive officers of SMEs internalize social cognition, they can achieve organizational transformation as desired. This study argues that SMEs have organizational readiness and can change as they spread their beliefs, products, or services to societies. Therefore, research hypotheses H2a and b were developed.

H2a: Social cognitions positively influence organizational readiness for SMEs.
H2b: Social cognitions positively influence organizational readiness for change for SMEs.

Firm characteristics refer to an organization's ability and performance with regard to gaining profits, increasing inventory turnover, servicing customers, and conducting social responsibilities, and are associated with managerial skill and competencies. This study argues that SMEs work like regular firms. Consequently, SMEs operate to achieve optimal performance, which varies among them. The variation of SME performance determines their organizational readiness and readiness for change. This study proposes that the firm characteristics of SMEs influence their readiness to be transformed to an advanced level. Therefore, hypotheses H3a and b were constructed.

H3a: Firm characteristics of SMEs positively influence their organizational readiness.
H3b: Firm characteristics of SMEs positively influence their organizational readiness for change.

Expanding on the development of hypotheses H3, this study argues that the financial characteristics of SMEs are akin to their firm characteristics. SMEs specify financial characteristics in their loan policy, probability of default,

credit policy, and the others. This study takes into account that the financial characteristics of SMEs determine their organizational readiness and readiness for change. It is argued that financial characteristics empower the dynamic capabilities and competitiveness of SMEs to expand their level of business. Therefore, hypotheses H4a and b were developed.

H4a: Financial characteristics of SMEs positively influence organizational readiness.
H4b: Financial characteristics of SMEs positively influence organizational readiness for change.

Innovators and entrepreneurs of SMEs lead businesses with the necessary knowledge to manage missions and goals, the expertise to identify and analyze the relevant and future potential business, and avoid environmental and business uncertainties. This study argues that entrepreneur characteristics profoundly develop organizational competencies of SMEs. These competencies enhance organizational readiness and readiness for change for SMEs. Thus innovators and entrepreneurs protect and guarantee business continuity. Therefore, hypotheses H5a and b were constructed.

H5a: Innovator characteristics of SMEs positively influence organizational readiness.
H5b: Innovator characteristics influence their organizational readiness for change positively.

Researchers argue that SMEs with organizational readiness have optimism and innovative ways to improve their businesses. If SME owners and executive officers embed their capabilities and competencies motivated by change, they can easily achieve organizational readiness for change. These motivations to change particularly stem from commitment and efficacy, and in turn, allow SMEs to transform. In other words, SMEs take into account organizational motivations and spirits, which are used to enhance their dynamic capabilities and competitiveness levels in facing future challenges. However, this study argues that SMEs with high organizational readiness are already changed. In other words, they do not require readiness for change organizationally because they are already in the changing process. Therefore, hypothesis H6 was formulated.

H6: Organizational readiness of SMEs negatively influences organizational readiness for change.

This research bundled all associations of these constructs into ordered-sequential logic reasoning in the Study Model, as seen in Figure 1 and Figure 2. These models explain and predict SME organizational readiness and readiness for change, influenced by their business characteristics and capabilities of SMEs in social networks and social cognition. Figure 1 presents the Research Model - 1. Model -1 is split into two models to precaution the collinearity between social concepts (social networks and cognition) and characteristics (firm, finance, and innovator). It, then, named the split model with Model -1 Split -1. It also presents another perspective, a second-order model, and then investigates robustness associations in Research Model – 2, to account for characteristics that changed into unidimensional ones. In other words, this study role all types of SMEs characteristics as a second-order model because of their business reflection.

Figure 2: Research Model 2

4. Research Method

Sample and Measurement

Using physical survey methods, data were taken from SME firms across Indonesia from May to October 2019. This method is intended to improve the accuracy of data responses. We believe that this method is used to capture the real phenomena of SME firms in Indonesia. The data collection was based on a purposive sampling technique. Teddlie & yu (2007) suggested defining the criteria to select data samples that support the missions and goals of the research. Therefore, this study specifies certain criteria as below.

1. This study selected SMEs that gain either operating profits or total comprehensive profits.
2. It also selected SMEs that have account payables or long-term debts that are used for long-term investments. Researchers did not differentiate between sources of debts such as banks, the government, or rural credit.
3. The study chose SMEs with total assets equal to or above IDR 500 million. It considers those SMEs which had related to either commercial banks or credit institutions.

4. Finally, SMEs that are financial institutions—conventional and sharia—were excluded. Researchers argue that these SMEs did not entirely depend on production costs, which were material resources or labor costs.

First, this study adopted variable measurements of social networks and networking from Chen et al. (2019); Fatoki (2011); Horak et al. (2019); Jones & Volpe (2011); Lee et al. (2010); Mehreen et al. (2019); Wasserman & Galaskiewicz (1994); Yamin & Kurt (2018); and Zhou et al. (2007). This variable comprised questions regarding experience, involvement in the profession, relationship with the governmental institution, disclosure of financial reporting, customer relationship, and post-sale services. Second, this study took into account Bandura (1986, 1988, 1989, 2008). This study considered all variables in these extant research of social cognition. The indicator of SME owners' and officers' knowledge was used to justify their capabilities, competencies, and self-efficacy. Third, it posits Chelliah et al. (2010); Durrah et al. (2016); Moreno et al. (2010); Noori et al. (2017); Stanwick & Stanwick (1998); Tongli et al. (2019); and Wincent (2005). This study considered the measurements of the firm's financial profits, return on invested capital, market share, and business size. Fourth, this study refers to Beck & Demirguc-Kunt (2006), who use the financial characteristics of SMEs, including debt-to-equity ratio, interest rate, turnover, and probability to be bankrupt. Fifth, this research examines innovator or entrepreneur characteristics. This variable measures their potential benefits, strength, weaknesses, opportunities, threats, skills and expertise, methods for searching debts, and environmental fit. Sixth, the study considered organizational readiness of SMEs by using variables suggested by Coleman et al. (2019); Pruitt (2015); Puklavec et al. (2018); and Walker et al. (2016), specifically, endowment capitals of optimism and innovativeness. Comfort and security can help SMEs face environmental uncertainties and pressure. Seventh, this study builds on work by Armenakis et al. (1993, 1999); Cunningham et al. (2002); Heckmann et al. (2016); Helfrich et al. (2009); Holt, Armenakis, Feild, et al. (2007); Holt, Armenakis, Harris, et al. (2007); Lizar et al. (2015); Shea et al. (2014); and Weiner (2009) to develop the variable of organizational readiness for change with two leading indicators—the SME's internal beliefs for changing commitments, and efficacy for change. Finally, this study designed all variables with ordinal choices in questioners with answers ranging from Strongly Agree (SA), Agree (A), Neither Agree nor Disagree (N), Disagree (D), to Strongly Disagree (SD).

Statistical Tests

After data were collected, the variables were tested for reliability using Cronbach's alpha, and the model was tested for validity (Cooper & Schindler, 2014; Hair et al., 2014). Thus, this study investigates the regularity of data that was collected using proper measurement instruments. After the initial stage, convergent and discriminant validities were simultaneously examined, and it was found that each indicator instrument could differentiate within-construct and cross-construct. In other words, it could achieve convergent and discriminant validities that could be manipulated by deleting indicators that were not optimally reliable or valid. This study, therefore, infers that all variables are eligible to be used to accomplish the research objectives due to the absence of data bias. Regardless of whether the examination results of reliability and validity tests fulfill standard values, this research continues to investigate nomological validity (Kline, 2015; Teddlie & yu, 2007). The model's goodness-of-fit was examined using Chi-Square- X^2, CMIN/DF or Relative X^2, Comparative Fit Index (CFI), Tucker Lewis Index (TLI), and Root Mean Square Error of Approximation (RMSEA). This study took into account normative standards used to determine the goodness-of-fit level, as suggested by Hancock & Mueller (2013); Kaplan (2008); Kline (2015); and Teddlie & yu (2007).

5. Statistical Result and Discussion

Demography and Descriptive Statistics

This study was conducted on 711 respondents, of whom seven were eliminated due to incomplete data fulfillment. The final sample of 704 represented all regencies in the Indonesia area and was collected using a direct-physical survey by visiting each respondent. The authors explain that the selected provinces are randomly due to easiness

in transportation. Table 1 reports the data arrays. The authors acknowledged that Indonesia is spread over 34 provinces and comprises almost 64 big cities, of which 18 cities (regencies) common to SMEs were chosen. It was noted that Pontianak city supported this research data as 52 SMEs or 7.39%. Table 1 shows others at 204 (28.98%). The data on others' are from many cities that contribute no more than ten SMEs.

Table 1 Research Data and Demography

Categories	Explanations	Numbers	Percentage
Regions (Provinces)	Banjarnegara	45	6.39%
	Magelang	26	3.69%
	Karanganyar	11	1.56%
	Klaten	16	2.27%
	Kebumen	22	3.13%
	Kudus	43	6.11%
	Purworejo	19	2.70%
	Sukoharjo	38	5.40%
	Surakarta	23	3.27%
	Temanggung	21	2.98%
	Wonosobo	22	3.13%
	Madura – Bangkalan	48	6.82%
	West Kalimantan – Pontianak	52	7.39%
	North Sulawesi – Manado	19	2.70%
	North Sumatera – Medan	25	3.55%
	Yogyakarta – Bantul	13	1.85%
	Yogyakarta – Yogyakarta	31	4.40%
	Yogyakarta – Sleman	26	3.69%
	Others	204	28.98%
Ages of Business	1–3 years	98	13.92%
	4–6 years	137	19.46%
	7–9 years	78	11.08%
	More than ten years	300	42.61%
	Others	91	12.93%
Business Legal-Form	Co-Operation	12	1.70%
	Limited Company	49	6.96%
	Limited Partnership	105	14.91%
	Personal Firm	3	0.43%
	Others	535	75.99%
Positions of Respondent	Owners (Innovators)	518	73.58%
	Top Executive officers	112	15.91%
	Others	74	10.51%

This research took into account 300 SMEs (42.61%) than had existed for at least ten years, indicating that they had long struggled to sustain and maintain their businesses. This data was considered attractive because some SMEs did not shape their business as per Indonesian law. In all, 535 (75.99%) SMEs did not manage their business as per legal regulations. This study documented 518 (73.58%) SME owners who were interested in this research. SME owners profoundly respected all kinds of studies due to their appreciation of science and knowledge. From another perspective, the higher proportion of SME owners responding to questionnaires indicated that they still managed their business and were completely responsible for improving themselves.

Data collection was followed by data analysis. Table 2 reports the descriptive statistics for 704 respondents with all variables that had mean values not dominated by differences. The median values were approximately 4.00. Moreover, standard deviations of these variables were relatively similar, with 0.437 as the lowest value in the innovator characteristics and 0.593 as the highest in social networks. This study, therefore, inferred that mean, median, and standard deviations among those variables are likely identical, except for the variable of financial characteristics.

Table 2 Data Descriptives

Variables	Min.	Max.	Mean	Median	Std. Dev.
Social Networks	1.00	5.00	3.987	4.00	0.593
Social Cognitive	1.00	5.00	3.721	3.80	0.587
Firm Characteristics	1.00	5.00	3.639	3.67	0.583
Financial Characteristics	1.00	5.00	3.403	3.33	0.564
Innovator Characteristics	1.00	5.00	3.927	4.00	0.473
Organizational Readiness	1.00	5.00	3.784	3.86	0.522
Organizational Readiness for Change	1.00	5.00	3.942	4.00	0.517

Note: n: 704 respondents

Validity and Reliability Test Results

This study examined the collected data to measure its validity and reliability. The statistical analysis showed that KMO values for all variables exceeded 0.500 and were close to 1.000. Thus statistical results found that each variable has a distinct value, and each variable loaded each item question proposed by the research. The lowest KMO value, at 0.733, is the variable of social networks. However, this KMO value fulfilled that standard (Cooper & Schindler, 2014; Hair et al., 2014). Thus, this research data fulfilled the convergent and discriminant validities. This study also measures sampling adequacy with the column of MSA values. Table 3 indicates that MSA values for all variables resulted in more than 0.500. This research concluded that all variables had set their values without errors, which were influenced by others (Cooper & Schindler, 2014; Hair et al., 2014). Thus, this study met the convergent and discriminant validities.

Table 3 Results of Validity and Reliability Tests

Variables	Items	Corrected Item - Correlation	KMO	MSA	Factor Loading	Cronbach's Alpha

	FnCh.6	0.628		0.872	0.592	

Note: Kaiser Mayer Olkin (KMO); Measure of Sampling Adequacy (MSA)

This data achieved standard reliability because all values of Cronbach Alpha were more than 0.600 (Cooper & Schindler, 2014; Hair et al., 2014). The lowest value of the reliability test was 0.749, which is the variable of social networks. It meant that the collected data were equivalent to what this study proposed to measure all variables. It also meant that this research got high data reliability. Further analysis was conducted after the fulfillment of validity and reliability.

Statistical Results

Table 4 shows statistical results for all causality tests of the hypotheses. All hypotheses were supported at a 1.00% significance level, except for hypotheses H3a and H3b in Research Model -1. Hypotheses H4a in Research Model -1 is not supported, but it is supported in the Research Model -1; Split -2. Hypothesis H1a proposed that social networks positively affect organizational readiness. Statistical results supported this hypothesis with the coefficient value of 0.713 and the CR-value of 10.068. Hypothesis H1b suggested that social networks positively affect organizational readiness for change. It is positively supported by the coefficient value of 1.509 and the CR-value of 9.158. Both hypotheses are statistically significant at the level of 1.00%. Hypothesis H2a is positively supported by the coefficient and the CR-value, which is 0.394 (12.413). Hypothesis H2b is also positively supported by the coefficient and the CR-value, which is 0.388 (5.994). This study concluded that social networks positively associated with either organizational readiness or efficacy for change.

Table 4 Statistical Results

Hypotheses		Causality	Model -1		Model -1; Split -1		Model -1; Split -2	
			Coeff.	CR	Coeff.	CR	Coeff.	CR
H1a	(+)	SN → OR	0.713	10.068***	0.766	10.602***		
H1b	(+)	SN → ORC	1.509	9.158***	1.597	9.278***		
H2a	(+)	SC → OR	0.394	12.413***	0.425	12.972***		
H2b	(+)	SC → ORC	0.388	5.994***	0.439	6.234***		
H3a	(+)	FCh. → OR	-0.023	-0.964			-0.206	-7.620
H3b	(+)	FCh. → ORC	-0.007	-0.227			-0.581	-4.903
H4a	(+)	FiCh. → OR	0.046	1.464			0.044	1.351***
H4b	(+)	FiCh. → ORC	0.018	0.443***			0.100	1.092***
H5a	(+)	ICh. → OR	0.189	4.629***			1.570	12.209***
H5b	(+)	ICh. → ORC	0.384	6.049***			4.840	6.112***
H6	(-)	OR → ORC	-0.742	-5.376***	-0.733	-5.237***	-2.256	-4.954***

Note: Social Networks (SN); Social Cognitive (SC); Firm Characteristics (FCh.); Financial Characteristics (FiCh.); Innovator Characteristics (ICh.); Organizational Readiness (OR); Organizational Readiness for Change (ORC). ***; **; *: statistically significant at levels of 1%, 5%, and 10%, respectively.

This study failed to support hypotheses H3a, H3b, and H4a. It inferred those firm characteristics did not influence either organizational readiness or change. It also failed to support the hypothesis H4a in Research Model -1 but succeeded that H4a in Research Model -1; Split -2. Thus, SMEs' financial characteristics somehow influence organizational readiness for change. It, therefore, inferred that financial characteristics affected the SMEs' readiness for change even if they were not needed. The remaining hypotheses are supported as expected and statistically significant at the level of 1.00%. This study highlighted hypothesis H6 that stated the negatively associated SME's organizational readiness and change with the coefficient value of -0.742, -0.713, and -2.256, respectively, and significant at the level of 1.00%. It raised an argument as to whether these SMEs had been effective in their organizational readiness; they did not intend to change their behavior due to creativity and innovativeness. In other words, these SMEs had done their learning to internalize both optimism and innovativeness when they want to enlarge their business (Chen et al., 2019; Coleman et al., 2019). Due to internalization, they had low motivation to adjust their readiness for change.

Table 5 Goodness-of-Fit Results

Criteria	Cut-off Standards	Model -1	Model -1; Split -1	Model -1; Split -2	Model -2
Chi-square	-	5443.257	3285.500	3032.866	3921.947
Probability	≥0.05	0.000	0.000	0.000	0.000
CMIN/DF	≤5.00	4.306	5.588	6.177	5.951
RMSEA	≤0.08	0.069	0.081	0.086	0.084
TLI	≥0.90	0.780	0.792	0.794	0.740
CFI	≥0.90	0.779	0.806	0.809	0.756
AIC	-	5671.257	3441.500	3172.866	4085.947

Statistical results for models' nomological validities are presented in Table 5. This study met all criteria that are almost close to a high goodness-of-fit. Statistical results showed that CMIN/DF for Research Model -1, which are split, are 4.306, 5.588, and 6.177, respectively, almost meeting the standard value. This table also showed for the transformed model in Research Model -2, which has a value of 5.951. It posits Revelle (2018) that the goodness-of-fit would be marvelous, meritorious, middling, mediocre, and miserable. The research models are in the meritorious level of goodness-of-fit. The values of RMSEA, CFI, and TLI were similar to standard values. Overall, the goodness-of-fit of all research model almost fulfilled the standard values at a meritorious level.

Therefore, it was concluded that this study achieved its nomological validity; statistical results were further interpreted.

Robustness Test Results: Re-Modelling on A Second-Order Factor
Failing to support hypotheses H3a and H3b, this study transformed Research Model -1 to Model -2. This transformation also intended to check the robustness results of the other hypotheses. When firm, financial, and innovator characteristics were employed as second-order factors, this study succeeded in supporting the association between characteristics and both organizational readiness and readiness for change. Statistical results showed that this association has coefficient values of 0.290 and 0.656, with the CR values of 6.486 and 5.334. Thus, characteristics, as a union of the SMEs' firm, finance, and innovator, affected organizational readiness and readiness for change. Some parts of SME characteristics somehow have collinearity with either social networks or social cognition. Nevertheless, variables of the firm, financial, or innovator characteristics have the possibility of collinearity with each other.

Table 6 Statistical Results of the Research Model -2

Hypotheses		Causality	Model -2	
			Coeff.	CR
H1a	(+)	SN → OR	0.200	6.585***
H1b	(+)	SN → ORC	0.577	7.056***
H2a	(+)	SC → OR	0.395	12.200***
H2b	(+)	SC → ORC	0.582	4.894***
H1,2,3(a)	(+)	Chr. → OR	0.290	6.486***
H1,2,3(b)	(+)	Chr. → ORC	0.656	5.334***
Refl.0		FCh. ← Chr.	1.000	
Refl.1		FiCh. ← Chr.	1.047	5.116***
Refl.2		ICh. ← Chr.	1.647	6.303***
H6	(-)	OR → ORC	-1.187	-4.302***

Note: Social Networks (SN); Social Cognitive (SC); Firm Characteristics (FCh.); Financial Characteristics (FiCh.); Innovator Characteristics (ICh.); Characteristics (Chr.); Organizational Readiness (OR); Organizational Readiness for Change (ORC). ***; **; *: statistically significant at the levels of 1%, 5%, and 10% consequtively.

The remaining associations are robust in the statistical results of the Research Model -2. This study also found that the association between organizational readiness and readiness for change for SMEs is consistent with previous findings in Research Model -1. Therefore, it was concluded that the SMEs' social networks and social cognition influenced either organizational readiness or readiness for change. The transformed model offered a more detailed explanation than the previous one. In other words, the model with the second-order factor could guide executive officers and owners of SMEs in enhancing and predicting organizational readiness and readiness for change.

6. Analysis and Discussion

First, this study found that most Indonesian SMEs were considerate of recommendations of social networks. Indonesian SMEs practiced networking and used it to enterprise their firm on both sides of the supply chain and customer relationship. By enterprising relationships, SMEs expanded their connectivity to reduce business risks as they could undoubtedly finance production or render services to customers. By these means, SMEs developed their organizational readiness. From another perspective, this study concluded that Indonesian SMEs conducted learning to support their enterprising processes. They enhanced intangible assets by capitalizing on their networking (Leask & Parker, 2006; Liu et al., 2017). Thus, this study evinced that most Indonesian SMEs remained sustainable through social networks and by networking (Chen et al., 2019; Mehreen et al., 2019; Yamin

& Kurt, 2018; Zhou et al., 2007). Thus, most Indonesian SMEs intensively pursued organizational readiness. Indonesian large enterprises, otherwise, have high organizational readiness and readiness for change due to their capital intensive and multinational corporation. However, all these SMEs contributed to Indonesia's GDP, which is approximately 57.8%.

Considering social networks and networking, most Indonesian SMEs are already at a state of organizational readiness as they possessed commitment and efficacy from their experiences facing competition and had achieved sustainability. Indonesian SMEs had thus actualized business with intangible capitals in the form of self-organizational commitment and self-organizational efficacy (Heckmann et al., 2016; Lizar et al., 2015). Therefore, Indonesian SMEs were committed to enhancing learning, networking, and enterprising in maintaining their ongoing concerns. By improving their learning and networking, Indonesian SMEs acquired efficacies that helped them withstand economic and environmental pressures. Because of withstanding pressures, most Indonesian SMEs possessed organizational readiness for change. Thus, they had intangible resources in the form of knowledge capital, which could be used as a strategic endowment to transform themselves into a higher business class.

In terms of social cognition, most Indonesian SMEs learned through social phenomena and improved knowledge through the learning process of capturing business opportunities. This study found the following shreds of logical evidence that most Indonesian SMEs conducted the act of learning (Bandura, 1988, 1989; Boudreaux et al., 2019; Wang et al., 2019). Most Indonesian SMEs produce their products and services in regional areas and sell them across Indonesia, capturing future potential business by considering areas. They also include the magnitude of demanded products or services, which are not over-production as well as shortage-productions, indicating that they measured their capacities in fulfilling customer demands. They controlled what was needed in terms of production inputs and utilized these inputs efficiently. This study concluded that most Indonesian SMEs managed their business organizationally due to the inducement of social phenomena (Bandura, 1988, 1989; Boudreaux et al., 2019; Wang et al., 2019). If they did not take into account the existing social phenomena, they failed to maintain their sustainabilities and ongoing concerns.

As a consequence of inducing social phenomena, most Indonesian SMEs constructed their organizational readiness and then readiness for change (Chen et al., 2019; Coleman et al., 2019; Norman, 1999; Pratibha Dabholkar, 1996; Walker et al., 2016). This study concluded that most Indonesia SMEs had developed and enhanced their capabilities, especially in self-regulation, self-reflectiveness, and vicariousness (Bandura, 2008). Thus, most Indonesian SMEs had taken into account the fact that social phenomena and problems had been induced by them organizationally. Continuously, Indonesian SMEs reflected their social learning to regulate themselves organizationally. They learned social phenomena to brainstorm new ideas, develop a new product, internalize knowledge, and achieve their mission and agendas. On the other hand, Indonesian SMEs largely practice what they have learned among other SMEs. This study, therefore, concluded that most Indonesian SMEs placed knowledge and learning as managerial preferences along with debts and capitals.

In another perspective of SME characteristics, this study highlighted that these characteristics somehow determined their organizational readiness and readiness for change. The characteristics of SMEs were defined using three dimensions of firm, finance, and innovator, which were combined into a unidimensional. The characteristics of SMEs did not precisely influence their readiness organizationally. This study argued that the business characteristics of SMEs were reflected in their social networks and social cognition (Coleman et al., 2019; Puklavec et al., 2014). It was highlighted that most forward-looking Indonesian SMEs possessed organizational readiness and that capturing both social networks and cognition is the spirit that motivates SMEs to reduce business risks. In other words, those SMEs acquired knowledge with their learning and enterprising that is useful to maintain sustainability (Durrah et al., 2016; Noori et al., 2017; Tongli et al., 2019). This study found that most Indonesian SMEs are not always motivated to reduce their business risks (C. Cant et al., 2014; Chittithaworn

et al., 2011) because they want to avoid environmental uncertainty and competitive pressures. This study took into account what SMEs lookout for as foresight.

Regardless of the different business characteristics and knowledge acquisition of Indonesian SMEs, it is inferred that most SMEs like to improve their social networks and cognitions. Thus, they searched and internalized social phenomena and problems chiefly (Coleman et al., 2019; Puklavec et al., 2018) without neglecting their needs of debts and capitals. In other words, this study inferred that most Indonesian SMEs primarily focused on innovativeness due to adaptability enhancements. With considering adaptative capabilities, most Indonesian SMEs could manage to maintain or slightly expand the business. This research, finally, inferred that most Indonesian SMEs had been developing and dynamically seizing then organizations dynamically. Most Indonesian SMEs had conducted organizational learning in their either managers, owners, or innovators.

7. Research Finding

This study found that the empowerment of Indonesian SMEs should be primarily focused on knowledge acquisitions without neglecting the needs of debts and equity capital for these SMEs. In this case, knowledge is related to all traits of social networks and social cognition. This study implied that knowledge acquisition would be useful for Indonesia SMEs to enhance their organizational readiness and readiness for change (Chen et al., 2019; Coleman et al., 2019). From another perspective, social networks and cognition recommend that learning is the supremacy for either individual or organizational capabilities. The capabilities of SMEs, which are improved by learning, are innovativeness stemming from social networks and searching opportunities as pieces of advice of social cognition.

The position of knowledge acquisition in the highest priority and has implications for regulators to facilitate most Indonesian SMEs when they want to accentuate business. These types of knowledge can guide SMEs to achieve their readiness and help them change organizationally. This study was restricted to two grand knowledge, which are a social network and social cognitive theories. Meanwhile, it invited knowledge that could enhance and broaden SMEs' organization in enlarging or conglomerating their business. This study concluded that Indonesian regulators must facilitate SMEs in relating to all dimensional traits of social networks and social cognition.

The Indonesian regulator, based on a social network, should provide the learning curriculum for all SMEs. In the curriculum, Indonesian SMEs could learn from each other (Mehreen et al., 2019; Yamin & Kurt, 2018; Zhou et al., 2007) when another SME had achieved its engineering, emergence, and transformation. The Indonesian regulator would better facilitate and serve these learning mechanisms. First, the Indonesian regulator should provide tools, media, and procedures for all SMEs to perform knowledge dissemination, communication, innovation, training, and management activity nationally. Second, with the first facilitation, the Indonesian regulator could capture SMEs' organizational cognition and social relationship and facilitate all SMEs, which are explained as an epistemic community or invisible college.

Meanwhile, based on SCT, the Indonesian regulator had to prepare a learning curriculum for all SMEs. First, the curriculum should facilitate all SMEs to improve their behaviors and make necessary adjustments. Each SME could learn how others had conducted business and achieved their goals. Most Indonesian SMEs, therefore, could gain insights into how they had to build and broaden their business organizationally (Bandura, 1988, 1989; Boudreaux et al., 2019; Wang et al., 2019). Second, the curriculum should allow all Indonesian SMEs to develop as an agency with self-regulating, self-reflective, self-proactive, and vicarious abilities. Thus, each SME could improve their organizational cognition, which is useful to resolve business problems.

If Indonesian regulators made an epistemic community that was accompanied by a learning curriculum, they could increase local and national capabilities simultaneously. In other words, most Indonesian SMEs already

possessed organizational readiness (Chen et al., 2019; Coleman et al., 2019; Norman, 1999; Pratibha Dabholkar, 1996; Walker et al., 2016) and readiness for change (Heckmann et al., 2016; Lizar et al., 2015). However, most Indonesia SMEs had some endowment knowledge, which helped improve the management of their business with high commitment and efficiency. It implied to the Indonesian government that economic transformation for SMEs is strategically defined as empowerment with knowledge supremacy. Therefore, an Indonesian regulator could play a strategic role in determining how SMEs solve problems, run their organizations, and accomplish their missions and goals successfully.

8. Conclusions, Limitations, and Future Research

This research investigated the sluggish transformation of SMEs in Indonesia. It succeeded in identifying and finding the cause of this sluggishness. It was argued that the transformation of SMEs needs empowerment of knowledge acquisition for executive officers and innovators. Most institutions in Indonesia focus on the financial perspective, which is not recommended. This research constructed a new model for SME transformation, which highlights the supremacy of knowledge empowerment. The authors put forward social networks, social cognition, and SMEs' readiness as well as readiness for change. These concepts are employed to highlight that most Indonesian SMEs need intangible capital, especially for organizational cognition.

This study evinced nomological validities in the Research Model -1. This model concluded that social networks, social cognition, firm, financial, and innovator characteristics could explain SMEs' readiness and readiness for change. This study found that the Research Model -1 is low goodness-of-fit. It, therefore, transformed into a new model—Research Model -2. The Model -2 constructed firm, finance, and innovator as second-order factors of unidimensional characteristics. This latest model showed that social networks, social cognition, and characteristics determined SMEs' readiness as well as readiness for change. This study concluded that the second model resulted in robustness. Therefore, it was concluded that the constructivism of SME organizational readiness had its validity.

From both sides of the research design and statistical conclusions, this study implied the needs of a new conceptual regulation from Indonesian regulators. The new theoretical regulation is a policy that could empower social networks and social cognition for all SMEs in Indonesia. This regulation did not only enhance social-intangible capitals but also developed SME readiness and readiness for change. In short, this new conceptual regulation controlled the empowerment of knowledge supremacy for all Indonesian SMEs, which could transform into large, mature business entities. Thus, the empowerment of SMEs thorough knowledge supremacy is a national-strategic role that could provide these Indonesian SMEs to run their business with high competitiveness levels and support the mission and goals of Indonesia's economic development.

The authors acknowledge that this study had high external and low internal validities. This research opens opportunities for further investigations. The first potential research is the use of experimental designs when executive officers and owners of SMEs are treated with problematic or beneficial cases accompanying either social networks or cognition. Another aspect that future potential research could explore is experimental designs for executive officers and owners of SMEs who in shock or facing a chaotic event. This treatment is used to measure differential behaviors due to a shock directed at reducing or increasing readiness levels. New research could be developed with qualitative research, focusing on what aspects of the SME's organizational cognition drive their commitment to change into a big, mature business. In other words, this new research investigated organizational cognition for executive officers and innovators at SMEs who have a strong motivation to transform their business or not.

ENTREPRENEURIAL PROJECTS' DEVELOPMENT: ALTERNATIVE SOURCES OF INVESTMENTS

Viktoriya Zabolotnikova [1], Irina Selezneva [2], Arzigul Nizamdinova [3], Tamara Mukhamedyarova-Levina [4], Sagynkul Praliyeva [5]

[1,2,4,5] Turan University, Satpaeva Street, 16a, Almaty, 050000, Kazakhstan
[3] Al-Farabi Kazakh National University, 71 al-Farabi Ave., Almaty, 050040, Kazakhstan

Abstract. This study aims at researching the possibilities of using alternative sources for financing small and medium-sized business projects. The main study method is a survey of 275 experts who are heads of small and medium-sized enterprises of the Republic of Kazakhstan. According to the obtained results, the access to financing is an urgent problem for most enterprises. Bank loans and overdrafts remain the main sources of attracting investments for the implementation of development projects. At the same time, a considerable number of companies that need financing were not able to obtain a bank loan or failed to obtain the full amount of the requested funds, and only a small part of the companies managed to raise the required bank financing. Companies face particular difficulties when attracting investments in startups. Despite the fact that nowadays there are many new options for financing startups, Kazakh entrepreneurs do not use them actively. In order to increase the chances for obtaining funds, companies must more actively attract alternative sources of financing for new projects. According to the survey, the most relevant sources of alternative startup financing for Kazakh entrepreneurs have been identified. These are grants, business angel financing, and crowdfunding. When implementing startups, companies can choose the most suitable financing option, or use several options.

1. Introduction

All entrepreneurs know that one of the biggest risks of owning and managing their own business is a financial risk. The first two years of a new business are crucial because almost two-thirds of the established companies fail during this critical period and stop their activity (Batashev et al., 2020). A new business cannot pay for personnel, materials, inventory, or marketing without a sufficient cash flow. If an entrepreneur does not have the resources to personally finance a business, financing needs to be arranged.

The sufficient access to the capital is one of the most important obstacles to overcome when establishing and developing a new business. Taking into account the important role of the entrepreneurship in ensuring the economic growth of the country, it is still not surprising that the strive to dilute the financial constraints faced by potential entrepreneurs is an important goal for central bodies around the world (Mazurina et al., 2020; Tarkhanova et al., 2020; Biryukov et al., 2020; Karshalova et al., 2018).

For example, in order to solve the problems of attracting financing, the government of the Republic of Kazakhstan pursues the policy aimed at developing and supporting the entrepreneurship. The measures of financial support for the entrepreneurship include loans from second-tier banks and microbanking, loans from the budget funds, partial guaranteeing of loans, leasing, etc.

At the same time, there is still a considerable gap between the need of business in investments and their actual offer. The lack of access to loans is one of the most important problems faced by Kazakh entrepreneurs because they are limited by the lack of collateral, the absence of the past experience of business valuation, and the occasional lack of the related experience.

Although bank lending is the most common source of external financing for many entrepreneurs, subject to considerable dependence on investment needs, traditional bank financing often creates problems for new, innovative, and rapidly growing small and medium-sized enterprises (SMEs) that have higher risk-return profile.

At the same time, in the world practice, there are alternative sources of investments that create an additional opportunity to raise funds. The strive of SMEs to improve the capital structure and reduce their dependence on borrowed funds substantiated the reasonability of studying alternative sources in financing entrepreneurial projects (Dudin et al., 2020; Auyezkhanuly et al., 2019).

Alternative sources of financing have not yet become widespread in the Republic of Kazakhstan due to the lack of active sites and investors, as well as the lack of government regulation instruments. At the same time, the use of alternative instruments will ensure the required financing of entrepreneurial projects by attracting private and currently inactive capital.

2. Literature review

The world of banking and financial services continues to change rapidly, and alternatives to traditional products and services are introduced more and more often (Daskalakis et al., 2013). Previously, financial technologies could be considered as applications of traditional financial services to the existing technologies, but today there are financial innovations with the involvement of previously unused markets (Abdulsale & Worthington, 2013).

Over recent years, the increasing number of financing options has become available for SMEs, although some of them are still at the early stage of development or are available only for few SMEs.

Alternative financial strategies are more and more important in assisting enterprises to meet their financial needs in the growth and contributing to the economy (Block et al., 2018; Serikbaeva et al., 2019).

Since the debt financing provides moderate return for lenders, and therefore it is suitable for low-moderate risk profiles, i.e., the companies that are characterized by stable cash flow, moderate growth, proven business models and access to collateral or guarantees, alternative financial instruments change this traditional risk sharing instrument (Eniola & Entebang, 2015).

These instruments consist of numerous and competing sources of financing for SMEs, including asset-based financing, alternative forms of debt, hybrid instruments, and equity instruments.

The transition to alternative financing channels is a reorientation to appropriate restructuring of debt and equity capital by providing the hybrid capital structure with a different degree of risk and return (Lawal et al., 2018).

The reasonability of using alternative sources of project investment depends on the risk-return profile, the stage of the business life cycle, management structure, and financial skills (Table 1).

Table 1. Suitability of Alternative Financial Instruments for Various Profiles and Stages of the Company's Activity

	Type of financial instrument	Company's Profile and Stage
Low risk/return	Asset-based financing (Kolpak et al., 2016; Bilgin & Dinc, 2019; Mol-Gomez-Vazquez et al., 2018; Zhang et al., 2019) – Asset-based lending – Factoring – Financing a purchase order – Warehouse certificate – Leasing	Startups Limited credit and no collateral firms Fast growing and strapped companies Companies with a solid customer base but high investments in intangible assets Venture and information-opaque companies Companies that often change their capital assets Commodity Producers and Traders
	Alternative financing (Parnes & Nippani, 2019; Gürtler & Neelmeier, 2019; Carbó-Valverde, Rosen & Rodríguez-Fernández, 2017) – Corporate bonds – Securitized debt – Mortgage bonds – Private placement	Large and medium-sized companies with stable profits and relatively low cash flow volatility Companies investing or using growth opportunities Companies that do not want the dilution of ownership and control Small companies with limited public market opportunities
Medium risk/return	Hybrid instruments (Svědík & Tetřevová, 2015; Tetrevova, 2009; Swedick & Tetrevova, 2014; Franke & Hein, 2008) Subordinated loans/bonds Quiet investor participation Profit sharing rights Convertible bond Warrant bonds Mezzanine financing	Young fast-growing companies strive for cheaper expansion capital than venture capital, and for the weakening of control Created companies with new growth opportunities Companies undergoing the transition period and restructuring Companies striving to strengthen the capital structure Companies with well-established and stable profitability and market position
High risk/return	Direct investments	
	Business angel financing (Granz et al., 2020; Block et al., 2019; Ang et al., 2018) Crowdfunding (Mollick, 2014; Gruzina et al., 2016; Lehner et al., 2015) (equity)	Companies at the initial and early stage Innovative enterprises requiring investment and business building skills
	Venture capital (Repullo & Suarez, 2004; Rutskiy et al., 2020; Frank et al., 2008)	Companies at the initial, early and late stages of investment Companies with high growth potential that can generate high profits in a short time

	Other private investments (Brown et al., 2017)	Mature companies restructuring or changing ownership
		Companies in troubles with the rescue potential
	Public capital (Macaulay, 2019; Aust et al., 2020)	
	Specialized platforms for public listing of SMEs	Young, innovative, and risky small companies
		Companies with highly structured management systems and extensive disclosure

Thus, scientific references rather adequately cover the theoretical aspects related to the development of alternative sources of financing. However, there is insufficient number of studies on financial and nonfinancial barriers that hinder their use in investing entrepreneurial projects.

This study aims at investigating the barriers to financing entrepreneurial projects and identifying the possibility of attracting alternative sources of investment in the Republic of Kazakhstan.

The hypothesis of the study is the assumption that a more diversified set of financing options will allow SMEs to attract additional financial resources for the implementation of business projects.

3. Methods

The study is based on qualitative indicators obtained as a result of surveying 275 companies in the Republic of Kazakhstan.

The sample companies were randomly selected from the business register of the Republic of Kazakhstan (Businessnavigator, 2020). The sample was formed in order to ensure the comparable data accuracy for 155 small (21 – 30 employees) and 120 medium-sized (101 – 150 employees) Kazakh companies.

Typical SMEs included in the sample were SMEs with different business experience: 21.8 % of the surveyed companies had been operating for less than six months, 23.6 % – from six months to one year, 48 % – from one year to three years, and 6.6 % of the respondents had more than three-year experience.

The industry sample structure was as follows: trade enterprises – 38.2 %, construction companies – 23.3 %, transport and warehousing companies – 17.1 %, accommodation and food companies – 13.1 %; and industrial enterprises – 8.4 %.

The answers were given by the senior management (as a rule, the business owner or managing director) that could directly talk about financing the business under consideration and were either fully or partially responsible for financial decisions in their company.

The survey was carried out as a questionnaire with ten questions. In questions No. 1, 2, and 5, the respondents were asked to indicate the relevance of a particular problem according to the scale from one (not relevant) to ten (extremely relevant). After the survey, each response was analyzed and processed.

4. Results

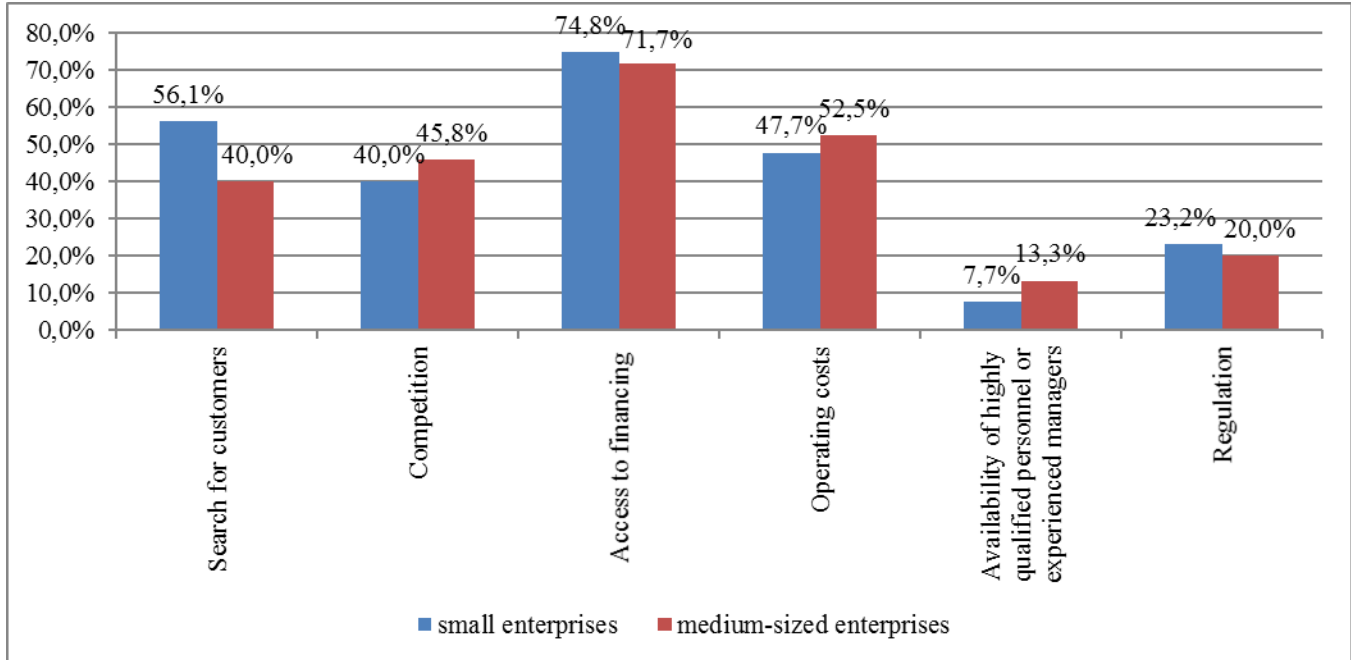
According to the survey, the access to financing as the main obstacle to business development is identified by more than 70 % of the surveyed experts (Figure 1).


Fig. 1. The most important problems faced by Kazakh SMEs
Source: Compiled by Authors

The access to financing was a more relevant problem for small enterprises (74.8 %). The access to financing as an important problem was noted by the experts from medium-sized enterprises a little less frequently.

Over the past 12 months, 73 % of the surveyed companies had used external financing. Approximately one quarter of the companies' representatives noted that they had not used external financing.

The experts called bank loans and overdrafts as the most relevant sources of attracting investments (Figure 2). About 54 % of the surveyed SMEs representatives considered bank loans, and 56 % considered bank overdrafts as relevant.
Fig. 2. The structure of financing of the Kazakh SMEs
Source: Compiled by Authors

Leasing and trade credit were also relevant for 46 % and 32 % of SMEs, respectively. In addition, 29 % of the respondents indicated that grants and subsidized loans, which involved support from government sources in the form of guarantees or other interventions, were important in financing their entrepreneurial projects.

Other loans, e.g., from the family, friends, or related companies, were important sources of financing for 21 % of the Kazakh SMEs. Internal funds were important as an alternative source of financing. This was indicated by 17 % of the experts. The share capital, factoring, other sources, and debt securities had impact on the access to financing of companies (safes) mentioned as relevant by less than 10 % of the SMEs.

About 46 % of the respondents (126 experts) believed that bank loans were not relevant. Sixty-two experts out of them (49.2 %) believed that their companies did not need this type of financing, and 11 % indicated that bank loans were not relevant due to high interest rates and other costs. Other experts reported other reasons of the inexpediency of bank loans (Figure 3).
Fig. 3. Reasons why bank loans are not relevant for Kazakh SMEs
Source: Compiled by Authors

About 42.5 % of the surveyed experts said that over the past year the needs of their companies in bank lending (with the exception of overdraft and credit lines) had increased.

28.7 % of the experts reported the decrease in the need in this type of project financing, which caused the net increase in needs by 13.8 % (Figure 4).
Fig. 4. Changes in the need for various types of financing to implement entrepreneurial projects in the Republic of Kazakhstan
Source: Compiled by Authors

The net increase in financing needs was noted on credit lines and overdrafts, trade loans, as well as in raising the capital by selling shares, including financing of business angels and venture financing.

The number of the companies that noted the decrease in need for such financial sources as leasing and other loans, including loans from friends and family, related companies, etc.

According to the expert survey, the largest investments were directed towards the implementation of projects related to the acquisition/renovation of fixed assets (36 %) and the replenishment of the working capital associated with the business expansion (34.2 %) (Figure 5).
Fig. 5. Objectives of using external financing over the recent six months
Source: Compiled by Authors

259

Other specific categories included the development and launch of new products or services (13.1 %), hiring and training of employees (13 %), and refinancing or repayment of obligations (14.2 %).

The survey results show that the percentage of the companies that need bank financing but did not obtain loans from financial institutions of Kazakhstan, is quite high and amounts to 25.8 % (Figure 6).
Fig. 6. Assessment of the availability of bank financing for Kazakh SMEs
Source: Compiled by Authors

According to the survey, almost half (49 %) of the SMEs had applied for bank loans, but were not financed as planned.

The experts noted that over recent years their companies had had more opportunities to use a wide range of alternative financing instruments, although some of those instruments had still been at the early stage of their development or in their current form had been available only to a small part of the SMEs (Figure 7).
Fig. 7. Use of alternative sources of financing by Kazakh SMEs
Source: Compiled by Authors

Thus, the results of the study show that, despite the relatively high need of Kazakh SMEs in external financing, alternative sources of investment are poorly used. This is largely due to the lack of financial literacy about the possibility to use these types of investments when implementing entrepreneurial projects.

5. Discussion

According to the study results, nowadays companies are sufficiently informed about the possibilities of using such alternative sources as leasing, crowdfunding, grants, subordinated lending, venture and business angel financing.
Fig. 8. Awareness of entrepreneurs about alternative sources of financing projects in the Republic of Kazakhstan
Source: Compiled by Authors

At the same time, rather high percentage of the respondents stated that they had had no idea about such financial sources as asset-based lending, mezzanine financing, warrant bonds, and subordinated loans.

According to more than half of the experts (53.5 %), the most promising sources of project financing for new and growing companies were grant financing (Figure 9).
Fig. 9. Promising sources of project financing for new and growing SMEs
Source: Compiled by Authors

State grants for entrepreneurial purposes are provided for by the *Enbek Program for the Development of Productive Employment and Mass Entrepreneurship for 2017 – 2021* and the *Business Roadmap* 2025 Unified Business Support and Development Program (BR-2025). According to the *Enbek Program*, state grants are provided in the amount of 200 MCI (monthly calculation index, 1 MRP – 2,651 tenge), i.e., this year it is 530,200 tenge. According to the BR-2025 Program, state grants are up to 3 mln tenge. According to the *Enbek Program*, the persons who have not previously obtained a grant under this program, including young people, members of low-income families, employable persons with limited liability, migrants and repatriates, can apply for a state grant. According to the BR-2025 Program, the applicants may be citizens who have an innovative business idea. Business angel financing (48.7 % of the respondents) and crowdfunding (45.5 %) can become considerable sources of attracting investments for newly created companies.

According to the study carried out by the European Trade Association, for business angels, seed funds, and early stage market players (EBANs), the main reason that reduces the willingness of business angels to invest is the high risk of failure (EBAN, 2018). Therefore, in the Republic of Kazakhstan it is necessary to create the relevant conditions for private investors. The mitigation of risk is a key element in achieving the goal, and the government of the Republic of Kazakhstan can use two instruments for this. In addition to creating a tax incentive scheme for investors investing in startups that allows them to deduct their taxes directly when investing, the creation of co-investment funds is an important political opportunity.

The launch of joint investment funds with business angels has proven to be an efficient way to attract "new money" in many countries, as well as expert knowledge from the market, helping to finance thousands of innovative companies (European Commission, 2016). Schemes of joint investment with business angels are of additional value to government bodies as compared to grants because their leverage is higher. Co-investment schemes are also valuable for angels because they reduce risk and allow more investments.

Usually, two scenarios arise as a result of creating the co-investment funds of business angels:

1) Public-private investment funds help to create investment communities at the early stages and, thus, create a favorable cycle. Private and public entities do not invest alone anymore. The investment risk is diluted on both sides, and also contributes to the perception of "political" risks.

2) It is possible to attract more funds for the ecosystem and more investments by combining several parties into a common financing mechanism. Management fees are also lower as compared to venture capital funds.

Some of the key features of co-investment funds that have impact on the community's successful understanding of business angels include asymmetric exits, tax incentives, and management fees.

In order to create conditions for the development of business angel financing in the Republic of Kazakhstan, it seems reasonable to consider the international experience in implementing measures to support this type of SEMs financing in some European countries (France, the United Kingdom, and Italy).

These incentives include government guarantees, lowered tax rates, or tax credits. It is necessary to note that wherever there are tax incentives, there is also considerable activity of business angels.

In France, business angels benefit from the reduction of income tax in the amount of 18 % of the investments. A new incentive measure for business angels to finance innovative companies, similar to PEAs adopted in other countries of the world is the SMEs innovation account (ICC). The SMEs innovation account aims at facilitating the financing of SMEs by deferring taxation on capital gains for the entire investment term.

In Italy, the capital gain obtained by business angels (residents and nonresidents) that is not related to the entrepreneurial activity is exempt from taxes if

a) The shares held had been personally renewed during the three years preceding the disposal,

b) The company the shares were granted to had been established not earlier than seven years prior to the disposal, and

c) The capital income is invested in acquiring shares in companies that are not older than three years old, and provided that they carry out the same entrepreneurial activity as the company whose shares were distributed.
The UK benefits from two schemes.

1) Assistance to entrepreneurs: it is mainly focused on entrepreneurs and provides for the first 10 mln pounds of the growth in lifetime income from the relevant business assets with the tax of 10 %.

2) Enterprise investment scheme (EIS):

In order to meet the requirements of venture capital funds, income tax benefits were increased, while the amount of advance tax benefits on income tax increased from 20 % to 30 %. In addition, the law provides for deferred capital gains tax (CGT).

According to 45.5 % of the experts, crowdfunding is a relevant source of financing. It is necessary to pay attention to its development.

Crowdfunding is a new source of financing startups that includes open calls to the public, usually via the Internet, to finance projects by making cash contributions in exchange for remuneration, pre-order of a product, lending, or

investing. Due to new information and communication technologies, crowdfunding lending-based platforms are a new way of financial intermediation by directly connecting lenders and borrowers through online platforms.

One of the biggest obstacles crowdfunding platforms face in their efforts to offer their services is the lack of common rules. This increases compliance and operating costs and prevents the expansion of crowdfunding platforms.

According to the analysis of the current practice of regulating crowdfunding lending platforms in the world, countries choose various regulatory approaches for crowdfunding lending-based platforms. A number of countries (France, Great Britain, and Israel) adopted special legislation that directly regulates the activities of credit crowdfunding platforms.

Other countries have introduced the crowdfunding regulation that is either applied to both credit and investment crowdfunding, or does not distinguish between the two business models (Austria, Belgium, Finland, Mexico, and Portugal).

In the countries where there is no lending-based crowdfunding regulation, platforms are adapted to the existing regulation of securities trading, banking or payment institutions. For example, in the Netherlands, consumer-business platforms must obtain individual permission for brokering from the Dutch Authority for Financial Markets, while consumer-consumer platforms require a lender license.

In Sweden and Denmark, credit platforms function as payment institutions, while in Norway they are registered as credit intermediaries. In France, where there is still a banking monopoly on consumer loans, a consumer-consumer platform had been licensed as a credit institution. In Estonia, consumer lending platforms are regulated as consumer lending by the financial supervisory authority, while consumer lending to businesses is not regulated. In Ireland, platforms operate without any legal status as a financial intermediary.

The experts recommend the following as priority measures that should be taken into account when developing the regulatory framework for the functioning of crowdfunding platforms in the Republic of Kazakhstan:

− To set minimum requirements to the capital. About 56.7 % of the experts believe that it is necessary to set minimum capital requirements to platforms. This is necessary for the platforms to be able to cover operating or compliance costs in case of a financial crisis.

− About 53.5 % of the experts noted that when determining requirements for the platforms, they should be obliged to maintain such systems and control means that would allow identifying, managing, tracking, mitigating, and reporting risks within and for their business. Risks may include operational risk, cybersecurity, personal data protection, and the risk that the platform can be used to commit financial crimes.

− According to 44.4 % of the experts, it is necessary to regulate the issues of platform responsibility for identifying, managing, mitigating, and reporting on conflicts of interest.

− More than 35.7 % of the experts mentioned that specific business conduct requirements should be regulated to ensure the proper disclosure of information to investors and issuers/borrowers for them to understand how the platform worked, especially the information about the methods of how the platform earned its income.

− According to 32.4 % of the experts, the law must guarantee that platforms can, but are not required to, offer automated instruments related to diversifying investor portfolios.

The above recommendations are an incomplete list of the best practices the experts should take into account when developing the regulatory framework that regulates the activities of crowdfunding platforms in the Republic of Kazakhstan.

Conclusions

The results of the study have confirmed the hypothesis set herein about the possibility of using alternative sources of financing in order to attract investments in the implementation of entrepreneurial projects.

The results obtained during the study make it possible to conclude that for 40 % of the surveyed companies, the access to financing is a limiting factor in their business development. At the same time, 42.5 % of the experts mentioned the increasing need for external financing. At the same time, for new start-up companies, the availability of bank lending remains low.

At the present time, there are many sources of financing that are a real alternative to bank lending. However, they have not yet been widely used in the Republic of Kazakhstan.

According to the experts, for the Republic of Kazakhstan, the most relevant sources of financing entrepreneurial projects, especially start-ups, include state grants, business angel financing, and financing from private lenders through crowdfunding platforms.

E-mails: [1] prokopenko.olha.w@gmail.com (Corresponding author)*

Abstract. The article aims at substantiating the importance and relevance of the "green shipping" concept, as well as updating approaches to its understanding in the context of the COVID-19 pandemic. Besides, the article discusses the tools by which there can be achieved the goals of the classical concept, as well as the tools that can be implemented as part of a so-called "primary block" – humanity-friendly part of the updated "green shipment" concept. The purpose of the article is to give grounds to promising areas of investment in "green shipping" projects under the influence of the COVID-19 pandemic, as well as to review the instruments to increase the biological safety of vessels to ensure the financial stability of shipment companies. This article explains the necessity to reconsider the "green shipping" concept, which, under the influence the COVID-19 pandemic, cannot remain the same any longer. The authors proved that achieving total ecological friendliness does not mean the full safety of shipping, and, in their opinion, apart from realizing other fundamental tasks, "green vessels" must become friendly to humanity. There are accumulated the main instruments, which are the part of eco-friendly shipping and are the objects of international investments, and there are proposed the fundamentally new ones. This paper creates the basis for further fundamental research aimed at updating "green shipping" concept under the influence of unfavourable economic and social environment in order to maintain financial stability of all stakeholders engaged in international investments in shipping.

1. Introduction

The development of modern society is impossible without some global, powerful and dynamic movers. As the population of the planet is constantly growing, these movers are permanently connected with satisfying our growing needs (Bashynska & Dyskina, 2018). From delivering passengers, their luggage and mail to transporting oil, natural resources, heavy machinery and unified containers – all these are the tasks to be solved. The dynamics of international economic relationships even during the last two decades gives us all grounds to believe that the role of cargo and passenger transportation increases each year. As an example, we cite the dynamics of growth in the world port container traffic, which has grown during the past decade from 500 mln. of twenty-foot equivalent units in 2000 to almost 800 mln. in 2018 (UNCTAD, 2019). The similar situation is observed in the cruise line transportation: for the last ten years the quantity of passengers carried by cruise liners has grown by the same 1.5 times – from 21 mln. of people in 2010 to 32 mln. in 2019 (Statitsa, 2019). However, if the rail and road transport have some obvious continental limitations to be used freely and air transport is pretty expensive and has frames of useful loading, a particular type of movers has unconditional benefits: high carrying capacity and huge consignments; the ability to deliver both people and goods over unlimited distances, and comparably lower tariffs. These movers are the global fleet, global shipping.

For the centuries, the fleet of passenger and cargo ships has created conditions for discovering new territories, finding new countries and providing further opportunities for their economic growth and development. The past six - seven decades, the volume of shipping has increased several times. Besides, a mighty industry of sea tourism has been created.

All facts mentioned earlier only prove the necessity and considerable economic importance of developed shipping in the modern world and, without any doubts, the world of the future.

The most general understanding of "green shipping" assumes using the resources and energy by different types of both cargo and passenger vessels in such a way that prevents pollution made by ships as well as reduces shipping impact on global environment (Viana et al., 2020).

The current situation, especially the problem of COVID-19 pandemic, highlighted that shipping might bring not only new opportunities but also severe difficulties and challenges to be tackled.

Another fundamental problem is to make investments and distribute international financial flows in the sphere of shipping. During recent years, a lion's share of investments has been sent to rebuilding, reconstruction of old infrastructure and designing a new one. Today, the ports of Shanghai, Singapore, Hong Kong, Shenzhen, Busan, Ningbo-Shoushan, Guangzhou, Qingdao are not only the cargo terminals but an alliance of thousands of companies and millions of people. Moreover, modern passenger terminals are real art masterpieces attracting tourists and providing the development of business both for local territories and countries as a whole.

As it was considered before, such concentration of people, simultaneously with significant opportunities, brought a lot of fundamental problems of environmental, social, economic and, without exaggeration, healthcare character.

Such kind of a situation dictates new requirements to vessel design, planning and construction of modern ports, which guarantee the safety and health protection for direct and indirect participants in the shipping process, as well as assessment of all risks brought by new challenges.

This is a big task for new investment flows and, obviously, may be solved during several next years. However, today, we see the direction of movement and know what problems are in priority to organize further investments.

This paper is devoted to the explanation of modern challenges and the search for tools to solve the problems mentioned.

2. Theoretical Background

The problems of investing in green technologies are thoroughly and deeply studied today by many scientists and practitioners. Special attention is paid in the literature to a relatively new trend in science, which is called the concept of "green shipping." Different aspects of investments into technologies as the part of Sulphur Emission Control Areas (SECA) with relevant calculations of NPV and WACC, ROV and ROA of such investments were estimated (Atari et al., 2019). The impact of shipment on the CO2 emission (Bhattar, 2019) was reviewed as to specificity of investments into innovations, port infrastructure, vessels, and shipment.

The role of modern shipment (Lauer et al., 2007) is considered in the process of spreading dangerous sulphate burden, black carbon burden, aerosols generating and radiation pollution. There is given exact characteristic of regional spreading of hazardous materials and the rate of biologic hazard at different parts of the planet. Another work by Lindstad et al. (2015) considers the main types of substances polluting the oceans and seas, analyses the influence of each of them on the atmosphere, hydrosphere and living organisms, as well as studies the contribution each of these substances to environmental pollution. It is shown how ecological aspects of shipping affect consumer choice (Prokopenko, 2011). It is also shown that the development of green shipping enhances the competitiveness of ports and other participants in shipping infrastructure (Kitzmann et al., 2020).

The article by Metzger and Schinas (2019) is dedicated to explaining the gap between the level of financing and the net present value within green investment projects. In the framework of investment projects in the field of green shipment, methodologies of the Fuzzy Pay-Off Method (FPOM) and the Centre of Gravity-FPOM (CoG-FPOM) are proposed.

An extremely important work by Prause (2019) is linked with assessing the risks introduced by realization of different projects of green jobs separately and prospects of green shipping as a whole. There was presented an in-depth analysis of this set of problems for the Baltic region. Another scientific paper (Ragusa, Crampton, 2020) discusses the experience of cooperation between the New South Wales Government and all stakeholders in the matters of environmental pollution in the framework of the "Clean Air" project. The study shows that there is a significant inconsistency in the rules and regulations on pollution of the government and enterprises of different industries, in which sea transport has a special place. This paper proposes the ways to reform existing approaches to providing clean air for each citizen.

There are considered the ways of re-equipping ships or building new ones (Schinas & Metzger, 2019) within the framework of the green shipping paradigm to achieve the goals of the International Maritime Organization (among which: increasing the efficiency and safety of sea transportation by introducing modern eco-friendly

technologies at vessels, decreasing of CO2 footprint etc.). Besides, the economic effect of mounting various kinds of green technologies on ships is analysed: eco-friendly vessels (Taehee & Hyunjeong, 2017), as well as infrastructure for the shipping organization are described. A review of the approaches to understanding the eco-friendly ships in different countries is given; also, a historical outline of the International Maritime Organization requirements and their diversification within the concept of green navigation are presented. There are discussed different scenarios and decision-making approaches (Vakili et al., 2020) in the framework of finding a reasonable balance between pollution caused by ships and their economic efficiency. Besides, the article focuses on noise pollution of shipping routes, which can have no less and, sometimes, even more severe negative consequences for marine ecosystems.

The influence of sea transport on air pollution and the hydrosphere in the Mediterranean region (Viana et al., 2020) is considered. The main threats posed by sea transport for this region's development in terms of environmental impact are studied. The negative effects of sea transport on bird populations are investigated (Wiese & Ryan, 2003). The volumes of fuels and lubricants that are annually sorbed by coastal birds' feathers are analysed. It is concluded that oil pollution of Newfoundland ecosystems occurs year-round, based on the fact that seabirds are polluted by emissions products, regardless of season, hunting, etc.

An in-depth list of those technologies that are now considered part of the green shipping paradigm and eco-friendly ships is presented in the article by Yildirim (2020), with an explanation of how these technologies can have a positive effect on the ecosystem of the seas and oceans. In-depth studies in the field of green shipping (Shi et al., 2018) have shown that technological research needs to be specially strengthened.

3. Research Objective and Methodology

The purpose of this article is to substantiate promising areas of investment in "green shipping" projects under conditions of the COVID-19 pandemic, as well as to review the instruments for increasing the biological safety of vessels in order to ensure the financial stability of shipment companies.

This research is informed by major publications on "green shipping" and sustainable development, publications of analysts linked with the problem of COVID-19 as well as the situation with passenger and military vessels engaged into the problems of the pandemic.

The following methods were applied in the research. In determining the essence of the "green shipping" concept, as well as its fundamental components, the methods of scientific abstraction, logical generalization, induction and deduction, as well persuasive methods were used. The article analyses the primary literature on the research topic to obtain results.

While forming blocks within the updated concept of "green shipping", the logical-structural analysis was used. Besides, the authors performed a qualitative analysis of the green shipping risks and concluded that threats to biological safety had increased dramatically. This allowed adding a biological safety block (or friendly to humanity) to the fundamental components of the "green shipping" concept. In the opinion of the authors, such changes should be made based on the additional analysis of the whole concept of sustainable development. As a hypothesis, conducting similar studies should lead to identifying an essentially new component of sustainable development in general, resulting from the impact of the COVID-19 pandemic.

When selecting the main steps of the primary unit in the "green shipping" system, the system-structural analysis was used. These steps should not be understood as those that must be performed strictly in the specified sequence. There is proposed a ranking of the actions based on a potential country that has significant problems with ensuring the concept of "green shipping" in general, and the biological safety of vessels, in particular. Each

country has its problems to be solved. This means that the priority of these steps depends on the level at which the government and the logistics business in each specific country consider the problems linked with the safety of shipment for the environment and humanity.

This research used the methods of analysis and synthesis, when selecting the instruments, investment in which will allow achieving a high level of biological protection, which will enable the shipping to remain safe and maintain its financial stability even under conditions of such a force majeure event as the COVID-19 pandemic. In particular, the authors studied technologies used in other spheres (applied physics, hydraulics, hydrodynamics) and analysed the possibility of their use for developing "green shipping". The state-of-the-art existing and promising technologies are shown.

4. Results and Discussion

4.1. The COVID-19-Caused Update of the Fundamentals of "Green Shipping" Concept

Sea transportation development dates back to centuries ago. During all this long period, it is impossible to estimate the total tonnage of cargoes delivered, as well as the number of people who reached their destinations. Today it is impossible to imagine Transatlantic route and the horizon of New Hope Cape without Sub-Panamax Class, Panamax Class or even Post-Triple E-Class container ship of 21000 TEU and thousands of enterprises depended on their work efficiency.

At the same time, intensification of shipping has brought an unexpected problem – a negative influence on the environment. According to the most general calculations, transportation is responsible for more than 2.5% of CO_2 emission coming from using energy, creates more than 260 tons of plastic garbage as well as of liquid wastes, which cannot be counted and which destructively influence ecosystems and species (Bhattar, 2019). The tragedy that happened with the Exxon Valdez tanker on 24 March 1989, when, according to different calculations, from 250 to 750 barrels of crude oil were spilt onto the Alaskan's shore, attracted close attention to the future of the shipping industry and shipbuilding in general. Such negative examples when shipment had such a horrible influence on the environment were the basis for designing a new concept – so-called "green shipping". This is why the most general understanding of "green shipping" assumes using the resources and energy by vessels in the way that prevents pollutions made by them as well as reduces the shipping impact on the global environment (Viana et al., 2020).

This concept became a huge leap of industry and one of the essential elements of corporate social responsibility bringing the corporate sector new opportunities – participation in a real green supplying chain (Atari et al., 2019).

As it was mentioned before, the concept of "green shipping" unites the following fundamental components (Fonseca et al., 2020):

- economic – "green shipping" must both be profitable and guarantee the expanded reproduction;
- social – "green shipping" must be a powerful facility to create working places, must provide equal accesses to business opportunities, as well as recreation and cultural opportunities for all people, which use shipment services directly or indirectly;
- environmental – all previously mentioned challenges must lead to the reduction of its impact on climate, ecosystems, nearshore territories to prevent its decisive contribution to global problems' deepening.

From this standpoint, we believe that the concept of "green shipping" is very similar to the most significant paradigm of the 21st century, proclaimed by the General Assembly of United Nations, – sustainable development. In our opinion, the concept of "green shipping" may be realized by introducing of the following tools (Table 1).

Table 1. The Instruments to Achieve the Concept of "Green Shipping" (the most innovative, in the authors' opinion, tools to be implemented as the part of "green shipping" concept are marked blue)

N	Measure	Explanation
1.	**Ballast-Free System**	research and development of new technologies to abandon liquid ballast in future to stabilize the ship and to set up its optimal draft.
2.	**Rebuild Existing and Design New Types of Ship Engines**	which can consume both low-sulphur fuel and liquefied natural gas (LNG) to reduce the air pollution with exhaust fuel. According to scientific estimates, using LNG will stimulate reducing carbon dioxide emissions by 19-24% with simultaneous declining of curb nitrogen oxide emissions by 85-95%.
3.	**Slow-Down the Delivery**	the overall intention to shorten the time of delivery brings overconsumption of high-sulphur fuel oil (HSFO), and indeed causes the air pollution made while shipping the cargo and especially passengers. The estimations described that an insignificant slow-down of ship's movement can consume more than twice less of HSFO than the maximum speed.
4.	**Using New Types of Propulsion**	More effective types of propulsions can increase the efficiency of engines, cut fuel consumption and, possibly, decrease the physical influence on the ocean's ecosystems. That means using and converting ships (from classical propellers) under azipods or water cannons (which previously could only be used on small vessels). The idea of these propulsions is not new by itself; however, they have not become widespread yet; at the same time they can save fuel during manoeuvring near the piers and in the open sea, reduce negative influence on the environment and people's health.
5.	**Using Antifouling Hull Paint**	Fouling on the ship's hull, as practice shows, influences its speed and fuel consumption negatively. Such specific ship hull coating reduces the tempus of organism's growth on it and helps to save up to 5-10% of fuel.
6.	**Heat Utilization**	Outdated technologies used earlier created a surplus heat. Modern technologies of heat utilization using heat exchangers bring opportunities to send such heat to boil water, to make steam and perform comfortable temperature in cabins and cargo areas or other technological needs.
7.	**Use Alternative Sources to Get Movement**	While wind generators are considered today as prospect source of free, ecologically-friendly energy, using sails as propulsion for the vessels becomes less popular; still, this way to transform wind energy into movement represents the almost infinite stock of useful progress, is very cheap and has virtually unlimited potential to implement. It does not mean that all commercial cargo ships or passenger liners must be re-equipped with sails; in this case, it is reasonable to install the wind propulsions only where it is possible from economic, maybe aesthetic, but mostly ecologic reasons.
8.	**Installing Exhaust Gas Recirculation Systems**	This technology allows making partial filtering of exhaust air and to use it twice or thrice in cylinders of a board engine. Besides, this approach decreases the nitrogen pollution of environment.
9.	**Introducing Supercavitation Systems**	Supercavitation is not a new, but, at the same time, not very popular technology due to impossibility to implement it on civil vessels a few decades ago. This technology is characterized with making a big air bubble around the hull of the ship, which creates the area of sparse environment and the boat is sailing partially in air conditions. This technology not only minimizes the friction force among the steel and water but also saves fuel and allows increasing the speed of a ship without any increase in fuel consumption. However, this technology is pretty expensive, requires a lot of R&D, is very complicated to implement and, which is more important, cannot guarantee the stability of such equipment set on board. At the same time, this principle is researched and has a big potential to be used in future.
10.	**Implementation of a Shipment Version of Car Euro Standards**	Starting from Euro 5 standard, all exhaust gas produced by car's diesel engines must be cleaned up by specific chemical - AdBlue liquid. Without any debates, this increases transportation cost; however, it really helps to make movement based on burning diesel fuel more ecologically friendly.
11.	**Partial or Complete Transition to Electricity-Powered Vessels**	The hull of modern commercial vessels, especially over the waterline, may represent dangerous squares to set the solar panels on it. Moreover, the desks, the walls even the glasses may include elements sensitive to sunlight. Thus, the ship becomes a significant generator of electricity. This electricity may be used to supply power to support electric motors. Thus, sailing during the day under direct sunlight may become extremely ecologically friendly and will provide serious economic effect.

Source: (Lauer et al., 2007; Metzger, 2009; Lindstad, 2015; Taehee & Hyunjeong, 2017; Furmaniak et al, 2019; Metzger & Schinas, 2019; Olaniyi et al, 2019; Prause et al., 2019; German airline, 2020; Miśkiewicz & Wolniak, 2020; Yildirim, 2020).
Lines 9, 10, and 11 are the authors' suggestions.

Approaches listed earlier can not only be used with the reason to make shipping friendlier for the environment. This only means that the human notions, full scientific and technological potential, principally other financial opportunities must be oriented on revolutionizing of shipping. That is why we believe that the "green shipping" concept is not only the list of goals, reasons and practical instruments but new economic philosophy which stimulates satisfaction of our increasing needs with simultaneous relief of environmental impact on the marine and air ecosystem.

The modern "green shipping" concept presumes unlimited opportunities in using various technological decisions, which can be realized based on economic, social and ecologic reasons. However, in our opinion, this system of relationships was oriented to reach such efficiency of shipping that allows protecting rights and interests of both current and future generations. Based on this standpoint, we concluded that the "green shipping" concept was a part of a higher-level concept – the concept of sustainable development (Ragusa, 2020).

The pandemic of COVID-19 highlighted a significant problem that modern society is still not ready to protect fully the rights of future generations. Unfortunately, humanity is still to solve another kind of a problem – protection of ourselves.

Gradual internationalization and globalization of humanity have created opportunities for the majority of people to make business and touristic trips on board a ship as well as to intensify the cargo turnover. Each year, the economic role of shipping increases, and during past years, commercial vessels services have accounted for more than 60% of international trade (Viana et al., 2020).

However, along with moving commodities to meet our needs, sea transport brought new dangers – a possibility to spread terrible viruses, like COVID-19. No matter what the shipping purpose is, – be it a passenger liner, commercial cargo or even military vessel – a ship is a closed space, and, hence, favourable for virus replication - just a few examples (see Figure 1).

Military vessels

1. USS Kidd destroyer with a crew of about 330 people, with about 20 sailors infected with the coronavirus.
2. Aircraft carrier US Theodore Roosevelt with a crew of 4000 people. The captain of the ship requested the possibility of isolation for the entire crew when it turned out that there were about 100 people infected on board.
3. According to open sources, the quantity of US Navy ships where infected sailors were discovered reached 25.

Passenger vessels

1. Diamond Princess Cruise Ship with about 4061 (passengers and crew) people on board – residents of 50 countries. By the end of February, a number of infected people reached 705.
2. Grand Princess Cruise Ship with about 3500 (2400 passengers and 1100 crew) people on board – residents of 54 countries. By the end of February, a number of infected people reached more than 130.
3. Ruby Princess Cruise Ship – 662 people infected, Greg Mortimer Cruise Ship – 128 people infected; Horizon Cruise Ship – 125 people infected; Grand Princess Cruise Ship – 103 people infected.

Figure 1. Some Examples of Ships with COVID-19 Diagnosed in People on Board
Source: The authors' research based on the data from Open Internet mass-media sources.

Just taking these data, it is easy to conclude that by the time when the first infected people were discovered, the total share of sick people on board has already amounted to 2.5-15%, and there is no guarantee that by this time some percentage of infected people have not returned to their native countries. The model of a virus further transmission (no mater of a kind: COVID-19, bird or swine flu) by the people who sailed on the ships or just communicated with infected passengers after their return can be built only with enormous approximations, which makes this model meaningless. Moreover, the disease can go on with and without symptoms. And there is no certainty that all potential COVID-19 carriers from these and other ships were detected on time and whether they were detected at all.

At the same time, there was also another situation where the Magnifica cruise liner became a shelter for 3,000 passengers who were afraid to go ashore and felt completely safe on board since there was no coronavirus there. It is an exception, of course, but it is an example when the ship becomes like a "doomsday shelter" – the shelter only for those people who are already on board.

This problem sharpens the concept of "green shipping", according to which today the vessels must be reviewed not only from their eco-friendly status for the environment, but also as a safe place for people's health and life (Schinas, 2019).

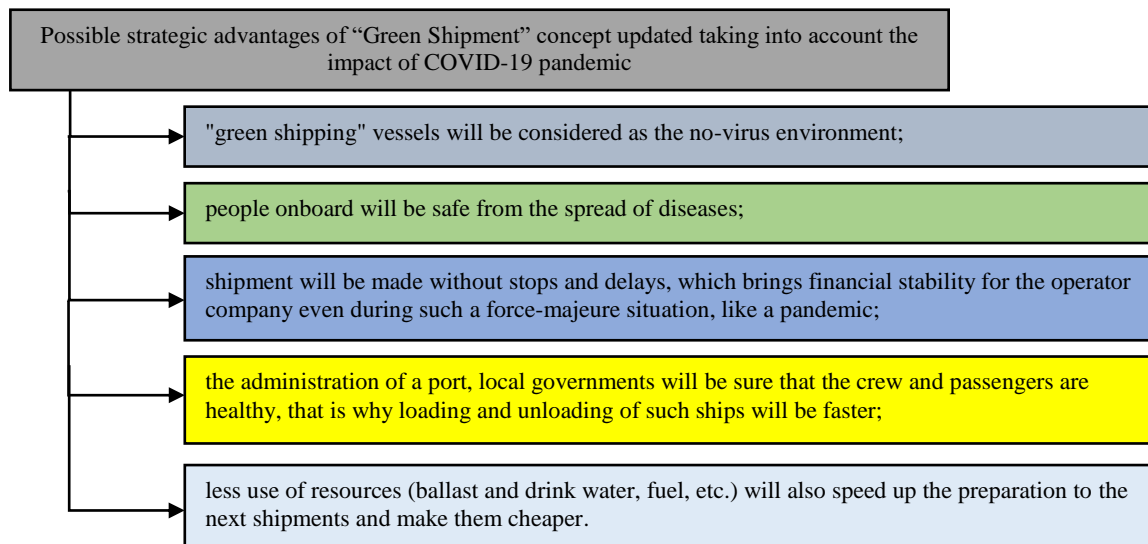
Different instruments can help reach this horizon. Their implementation will create strategic advantages for shipping, among which are (see Figure 2):


Figure 2. Advantages of the Updated Concept of "Green Shipping"

Source: developed by the authors.

Obviously, these initiatives require serious financing. That is why shipment companies along with international organizations, governments and shipbuilding companies must be ready to attract and accumulate significant investments (private, governmental, from international financial organizations) in order to ensure new norms of safety on vessels according to the updated "green shipping" concept, organize the powerful international team for doing R&D oriented to new technician conditions. Only such incentives, in our opinion, provide tangible results (Wiese & Ryan, 2003).

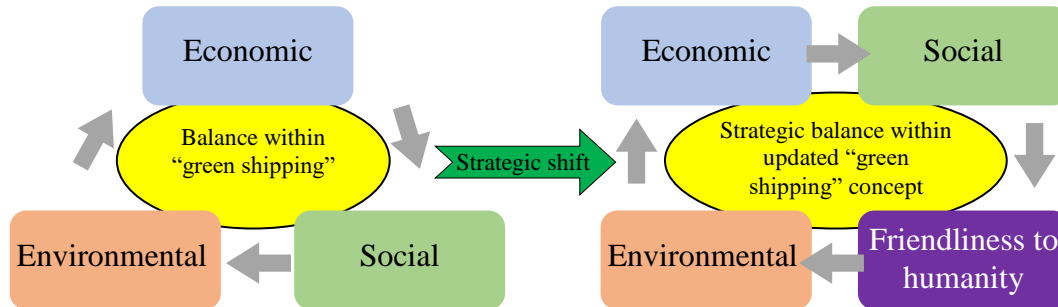
Thus, according to previously generated opinions, we believe that the "green shipping" concept, along with the fundamental components of sustainable development, must include another one – friendliness to humanity (Figure 3).


Figure 3. The author's approach to understanding the fundamental components of the updated "green shipping" concept, resulting from COVID-19 pandemic influence

Source: The authors' research, according to (Fonseca et al., 2020).
The block "Friendliness to humanity" is the authors' research.

In the opinion of the authors, given the COVID-19 pandemic influence, the 17 Sustainable Development Goals, approved in 2015 by the UN General Assembly, should also be expanded correspondingly.

4.2. The International Investments into "Green Shipment" under the Impact of COVID-19

First of all, we must research a new approach to understanding the essence of the "green shipping" concept. We believe that the renewed concept must not only be oriented on minimizing the negative effect of shipment business on the environment but also be formulated taking into account the impact of unexpected, force-majeure circumstance on the wellness of humanity (Ragusa & Crampton, 2020).

Based on this standpoint we suggest understanding the concept of "green shipping" as a fundamental model of growth and development within the shipment business that is oriented on protecting health, life and rights of humanity as well as using the resources and energy by different types of both cargo and passenger vessels connected with preventing pollution made by ships as well as reducing shipping impact on global environment (Prokopenko O. et al., 2020).

As we have already mentioned, the instruments that have been already successfully implemented in the frames of "green shipping" and which are the parts of the second block, further will be oriented on the investments to create and support an organization of the primary block.

According to our approach, the "green shipping" concept has two fundamental blocks (Table 2).

Table 2. Basic blocks of the updated concept of "green shipping"

Block	Explanation
Primary block	Protection of human rights. This means that vessels, no matter of their subordination and purpose, must be "human-friendly". Operator companies, governments, and international institutions must introduce all the necessary levers to protect the health and safety of people onboard and avoid the spreading of the biologic hazard from the board of a ship (diseases, viruses, insects, rodents etc.) to maintain the regular regime of life and protect from negative (destructive) consequences the national economy as well as national security.
Secondary block	Implementation of all possible instruments and technologies to reduce the burden on the environment, ecosystems, flora and fauna, to protect the right of future generations to live in the same (or better) conditions as (or than) the current generation. This block unites all previously existing approaches to understand this concept.

Source: The authors' research.

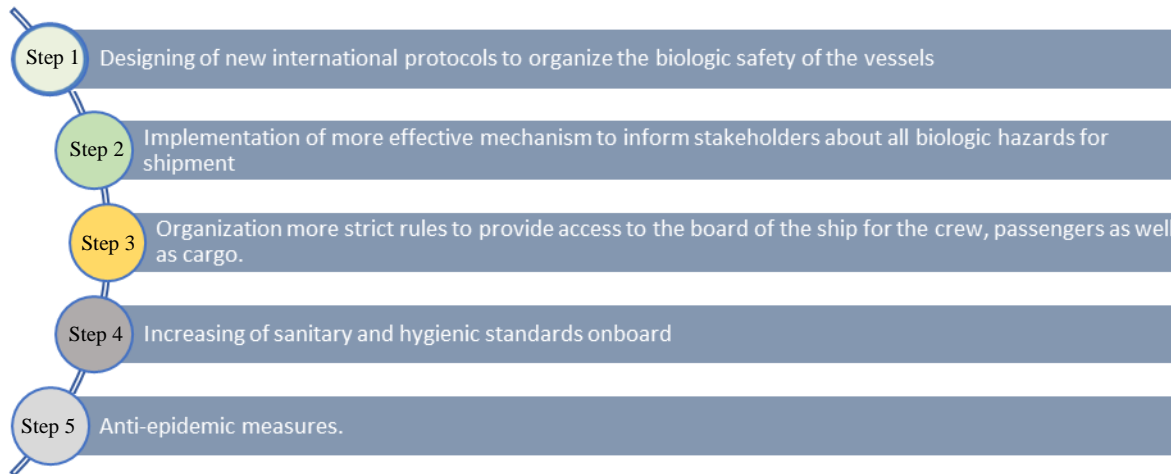
The most important directions which require a severe accumulation of international investments to attain all goals from the primary block are as follows (ranged by the rate of importance) (see Figure 4).


Figure 4. The Step-By-Step Mechanism to Implement the Primary Block of the Updated "Green Shipping" Concept

Source: developed by the authors.

We will describe those steps more precisely:

Step 1. Designing and implementing new international protocols to organize the biologic safety of the vessels independently of their conformation or inconsistency with classical postulates of "green shipping" concepts. Such contracts are to regulate the behaviour and interaction of all stakeholders engaged into a shipment process (from the port administration, port stevedores and loaders to vessels' crews and passengers) to provide the maximum level of their biologic safety. Another task to be solved within these protocols is a step-by-step plan to preventive diagnosing of possible biologic hazards coming from the boards of the ships as well as participants' actions if such a dangerous situation happens.

Step 2. Implementing a more effective mechanism to inform operator companies, logistic agencies and governments about all biologic hazards for shipment as well as about the choice of methods to avoid the penetration of these hazards onboard. This step means the necessity to design a global information system which will inform all kinds of stakeholders about the existing biologic dangers: within the mother country for both vessel and all crew members; within the destination country for cargo or/and passengers. All stakeholders

accredited to make shipment must obligatory be the members of this system and permanently monitor it according to the protocols reviewed in step 1. We propose to name this system the "Global Ship Information System on Biological Safety" (GSISOBS).

Step 3. Establishing stricter rules to provide access on board a ship for the crew, passengers and cargo. All people before the sea voyage must be monitored according to medical standards taking into account information from GSISOBS (step 2).

Step 4. Increasing sanitary and hygienic standards onboard (based on step 3):

● Daily express-monitoring the health status of the people on board;
● Making at least selective blood examination if the term of a sea voyage exceeds 5 days (every 5 days). The model of COVID-19 spread showed the virus incubation time of 4-5 days.
● Allocating mandatorily individual cabins with the highest level of biological protection for 2-3 patients. This must include all necessary infrastructure and tools for ship medical staff.
● Introducing a closed-cycle filtering and disinfection of ballast, technical wastewaters only using onboard equipment.
● Ensuring opportunities for primary sanitary treatment of a vessel in case pathogen is detected.

Step 5. Anti-epidemic measures. If stakeholders' efforts have not yielded results in the previous 4 steps, the highest-level protocol should be applied, involving the local government, medical services and (if necessary) international organizations in solving the problem. Information should be instantly placed in the system GSISOBS. The tools within this protocol may include isolation, quarantine for a crew and passengers, etc.

We understand the value of financial resources necessary to implement at least few of these steps; however, it is evident that an inevitable loss of profitability due to the reduction in the useful area of ships, introduction of complex (and expensive) onboard systems for monitoring, medical examination, laboratory tests, as well as disinfection, hiring and remuneration of trained personnel, possible delays cannot be compared with economic losses due to complete stop of production, and, hence, the sea delivery of goods and passengers.

We can take the case of Deutsche Lufthansa AG as an example. According to Carsten Spohr, the CEO of this airline, company loses €1 mln each hour (German airline, 2020). Of course, the airline is not a spaceship-operator company; however, we believe that losses there are even heavier taking into account the cost of infrastructure, vessels, expenditures for their support and the quantity of people engaged as well as third-side stakeholders.

Therefore, we believe that the above steps, although complicated and expensive to carry out, in a strategic perspective can ensure the financial stability of the companies/ship operators and make the ships genuinely consistent with the concept of "green shipments" – friendly with humanity an environment. In the end, COVID-19 pandemic shows that if our forces are not directed to protect people living today, there will be no future generations and the profitability of shipment business becomes the least problem for the future.

At the same time, we believe that it is not right to fight only those threats that result or may result from "green shipping". The problem of the COVID-19 spread showed that the solutions for dealing with global threats to biological safety must be searched in a complex. Moreover, the spread of this virus has shown that there is no global system of preventive measures that could effectively counter such threats. All, even the most modern, measures of protection and confrontation (AI tool, 2020; Leichman, 2020; Meisenzahl, 2020 and others) are only reactive, that is, those that are implemented only when the problem is already real and the mechanism of its aggravation has already been launched.

The problem is further aggravated by the fact that no one knows or can say what other problems we may face in the future. This is confirmed by the rate of incidence of COVID-19, which, in reality, no one expected.

From this perspective, we propose three measures, which should be aimed at combating potential threats and creating a mechanism for the first estimation of potential threats (Table 3). As we can see, such measures' implementation is a rather costly process, but nevertheless it is extremely important, since this is the only way for scientists to receive sufficient funding to conduct research with the aim of an early detection of corporate, national, regional, and global problems. It is important to add here that projects that are realizable within the framework of these measures may be: "green shipping", "green energy", "environmentally friendly production", "alternative fuel", "socially responsible business", in a word, everything that, in one way or another, is related to any type of activity, including the safety of maritime transport.

Table 3. The System of Measures to Create a Mechanism of estimating and preventing potential national, interstate and global threats

N.	Measure	Aims	Comment
1.	To form interdisciplinary groups of scientists at: International organizations (the UN, WHO, IMF, World Bank, International Maritime Organization, as well as all specialized organizations); at regional associations, free trade zones, trade associations.	1. to preventively estimate potential threats and risks for the global and regional economic systems; 2. to form strategies and recommendations for a effective beforehand response to these threats; 3. to distribute financial resources for scientific research between the priority sectors of science; 4. to evaluate the effectiveness of previous actions at global and regional levels.	Such groups of scientists should have at their disposal all means available to estimate potential threats: statistics, computing power, financial resources, as well as unlimited access to academic mobility. The main basis behind such a measure is a preventive nature. All their actions should be aimed at a timely estimation of threats and at designing effective mechanisms to minimize them. Such threats may include: potential distribution of diseases (threat of epidemics, pandemics); economic and financial crises; trade barriers, protectionism; protection of human rights etc.
2.	To form interdisciplinary groups of scientists at transnational corporations to prevent the harmful effects of companies on people, ecosystems, the climate in general and to prevent such an impact on the company itself.	1. to estimate potential threats and risks for the corporate activity; 2. to estimate the role and contribution of TNCs in deepening this threat; 3. to design tools to counter the aggravation of such threats; 4. to research perspective areas for the quality development of companies.	The corporate sector must realize that ill, unhappy, poor etc. employees cannot create additional value. Moreover ill, unhappy, poor etc. clients (consumers, customers) cannot bring economic effect or may be the source of biological hazard for the company itself. It is extremely important for the updated concept of "green shipping" – safety and economic efficiency of ports, sea terminals, and vessels. Funding for such groups of scientists should come from the company's net profit in the amounts set by groups of scientists at the international organizations and should not be abolished by the general meeting of shareholders.
3.	To establish an independent interdisciplinary fund of scientific grants to finance research and development in the field of national (biological, economic, financial, environmental, social) security at the government.	1. to do strategic estimate of sources of threats to the national security; 2. to ensure the ability to quickly form working groups of scientists to develop a set of measures to counter specific threats; 3. to prioritize research funding.	An independent foundation should be subordinate only to the head of the country and act only in the national interests. With the help of such a fund, operational funding (without bureaucratic barriers) can be received by those developments, the implementation of which would be too long without this fund or would not make sense in situations where the problem is already real, but the timely implementation of which should minimize or prevent the threat. Funding for such a foundation should come from the state budget and voluntary corporate investments. As business becomes more socially responsible, investing in such a fund is one of the most effective ways to deal with common problems for the whole country.

Conclusions

Summing up, it should be stated that the concept of "green shipping" is more relevant than ever. It proves that shipments are the driving forces of our progress, that without them the normal lives of ordinary people, as well as national economies and business development, are impossible. At the same time, ships can and do pose a threat to the environment, ecosystems and living organisms. Introduction of several measures (sometimes costly) can make existing and new ships more environmentally friendly, which will be useful both for the benefit of humanity, protection of the nature, and development of business itself, as the latest energy-saving technologies increase the efficiency when using resources, energy and fuel. This provides tangible savings, which is a tactical and strategic perspective guaranteeing not only shipping profitability but also financial stability for those companies that invest in such technologies regardless of the situation in the world.

The COVID-19 pandemic revealed yet another feature of the "green shipping" concept. Today, it is no longer enough just to ensure the environmental safety of ships, but also to implement appropriate measures to ensure biological security for the crew, passengers and cargo. Only the most abundant calculations based on information from open sources give reason to believe that at the time when the pathogenic organism is diagnosed in the first patient, 2.5-15% of people on board are already infected. This is a huge figure which suggests that any epidemic coming from the ship can spread very quickly in the country where passengers land or commodities are discharged.

This situation requires implementing serious measures to improve the biological protection for people on board ships and port workers. Such measures should include both developing appropriate protocols and financing specific equipment installation. Besides, the protocols should presume behaviour and relationship of the stakeholders involved in maritime trade and passenger traffic.

Such investments involve a wide range of stakeholders: ship operating companies, logistics agencies, representatives of ports, governments, as well as international organizations. Besides, this is a serious financial investment which in the operational future may lead to a specific decrease in profitability. However, such steps, in our opinion, are more acceptable than a complete shutdown of production, and therefore shipping, due to the spread of biological hazards.

The article covers the essence of the concept of "green shipping" and explains why this concept should be updated. For this purpose:

- a new understanding of the "green shipping" concept was formed;
- the connection between "green shipping" and the concept of sustainable development was substantiated, the influence of one concept on another was explained;
- the concept of "green shipping" was divided into two fundamental blocks and proposed tools, by implementing which it is possible to achieve the goals set in these blocks;
- within the framework of technological solutions, there were offered the newest means of "green shipping": introducing supercavitation systems, implementing a shipment version of car Euro standards, a partial or complete transition to electric-powered vessels;
- there was identified a new component that should enter into a single system with an economic, social, and environmental component - the element of friendliness to humanity.

Abstract. Innovation can be classified based on the type of its outcome which includes knowledge and technology, creative and cultural outcomes in addition to intangible assets. Innovation composite index is generally designed with the purpose of estimating the innovation capabilities and competencies of different governorates or regions. In this work, a governorate innovation composite index (GICI) is constructed and applied to the Egyptian governorates to evaluate the efficiency and effectiveness of adopted innovation measures and policies in these regions along with the assessment of the societal impact. Considering standard type of innovation composite indicators, the Egyptian index proposed in this work is conceptually broken down into a set of innovation inputs and outputs composing its production function. Inputs are divided into factors which are used to produce innovation output while considering specific enabling factors. The application of the innovation governorate index to the Egyptian context has delineated general as well as specific results. First, Innovation performance of governorates measured by the value of the composite index, shows a moderate attitude, whereas input sub-pillars for governorates are however on the low side. In light of this finding, Egypt's government needs to consolidate efforts towards enhancing the

---

capacity of innovation inputs. Second, the mean value of the governorates output pillar ranged from 53 to 99 percent. Based on this finding, the Egyptian government needs to adopt an integrated policy package to achieve the balance between input and output parameters of innovation. Finally, this paper suggests that the difference in innovation performance between regions should be considered as an important part in developing national innovation strategies.

Keywords: Innovation production function, composite index, regional innovation; benchmarking; innovation metrics.

1. Introduction

The recent *Oslo Manual* (OECD and Eurostat, 2018), defined innovation as "a new or improved product or process (or combination thereof) that differs significantly from the unit's previous products or processes and that has been made available to potential users (product) or brought into use by the unit (process)". This definition also includes the generation of new ideas, as well as the recombination of existing ideas. Given this rationale, the minimum requirements for an innovation must be new (or significantly improved) product, process to the firm (OECD,2018). Other international organisations such as the United Nations Educational, Science and Culture Organization (UNESCO) and the World Intellectual Property Organization (WIPO) have favoured also this definition (UNESCO, 2013).

Innovation drives economic growth, improves welfare of citizens, supports the transformation of countries to the knowledge era and helps to address social challenges (OECD, 2010a, Bassinini et al 2000, Pessoa 2010, OECD 2004 and 2010, EBRD 2019, Khorshid 2018, Khorshid and Ismail 2019). Innovation is considered a key driver to economic growth and competitiveness. Many traditional industrial economies are now in the process of transformation to a knowledge Economy, where innovation is considered one of the mains drivers for the transformation process, as well as a major factor for sustained economic development (Grupp and Mogee, 2004). Furthermore, many countries today are developing national plans in order to enhance their innovative capacity, with an aim to improve the growth prospects of their economies (Porter, 1999). The outcomes of innovation are often measured in terms of creative outputs such as , significant increase in sales from new products, significant reduction of a manufacturing processing time or the frequency of new product launches (Sofka, 2010, Laursen, 2006).

Innovation activities does not occur only in business sector or industrial companies but can also happen in any non-profit organization, cities, governorates, regions and countries at large. International studies show different levels of composite innovation indicators, such as product or process innovation, creative services, marketing and organisational innovation (Radwan and Sakr, 2018). Moreover, innovation generally requires collaboration with different stakeholders for knowledge, technology and risk sharing. An important type of innovation refers to the ability to make major improvements and modifications to existing technologies, or create new technologies (Furman, 2002). Many studies have been trying to measure innovation through creating an innovation complex index. An innovation index is a concise quantitative measure of the innovative capability of institutions, businesses or countries (Aspen Institute Italia 2007).

Moreover, composite innovation index represents a tool to measure, monitor and promote progress of the innovation performance in a company, region or country. The index could also serve as a quantitative benchmark highlighting the interaction between inputs and outputs of innovation and could help to assess policy means needed to boost innovation, to achieve economic growth and create new jobs. Furthermore, composite innovation index highlights policy challenges, and support the development of policies to draft new national innovation strategies (Jarunee, 2010).

On other front, innovation statistics can be used to evaluate the effectiveness of government public science and technology policies, and to compare the position of countries regarding innovation performance. Recently, several studies have developed composite innovation indices over the years to assess countries' positions and to evaluate the effectiveness of governments' interventions regarding innovation policies and strategies (Mahroum & Al-Saleh, 2013). Thus, several international institutions developed a range of innovation indices, (the European Innovation Scoreboard, the National Innovative Capacity Index from the World Economic Forum, the UNCTAD's indices, the Innovation Index of the World Bank, the Nordic Innovation Monitor, the OECD Science, Technology and Industry scoreboard, the Bloomberg Innovation Index, and the global innovation index or GII (Mahroum & Al-Saleh, 2013).

The analysis of composite indices helps policymakers and governments throughout the world to identify paths for future design and development of innovation policies. Based on recent literature, innovation is measured at different levels, starting from the level of a world geographic region, a country, a locality, a city or a company. In the recent years, we can find many studies aimed at measuring innovation at the city level, (Ergasakis et al., 2004), and others have developed specific metrics and indicators to provide a comparative assessment of the innovation performance of nations and regions (Dvir and Pasher, 2004; Metaxiotis et al., 2006; Scheel, 2011).

The purposes of this paper are; (i) to identify and articulate the linkages between innovation, research and development (R&D), science and technology strategies and economic development, (ii) to develop the multidimensional conceptual model of innovation, (iii) to assess alternative approaches to construct a composite innovation index, (iv) to develop a conceptual model for estimating a governorate innovation composite index (GICI) and (v) to use this model to estimate a composite index along with its inputs and outputs for the Egyptian governorates, and finally, (vi) to assess the innovation efficiency, effectiveness and impact of Egypt's governorates based on the developed composite index and its pillar, sub-pillars, sub-indicators and variables. Given these analytical objectives, the paper is organized around four sections. The first section summarizes the role of innovation in socioeconomic development, identifies the multi- dimensional structural model of the innovation process, and explains alternative approaches for its estimation and assessment of its impact. Section two develops the conceptual structure of the governorate innovation composite index (GICI), particularly constructed to evaluate innovation inputs and outputs of the Egyptian governorates, and describes as well the methodology used to estimate its pillars, sub-pillars, sub-indicators and Variables. Section three is devoted to the analysis and discussion of the obtained results. Finally, section four includes the concluding remarks and policy recommendation, followed by the list of references.

1.1. Innovation for development

In the Oslo Manual developed by OECD in 2005 and adopted by the UNESCO, innovation is defined as "creative activity leading to the development of new (or significantly improved) products (goods and services), processes, marketing methods and organizational models" (OECD 2005, UNESCO 2017). In the recently developed OSLO manual of 2018, the revised definition states that " innovation is a new product or process which differs significantly from the product previously delivered to consumers or the process previously used by the company

or the industry (OECD and Eurostat 2018). Based on this recent definition, OSLO Manual makes the difference between "Product Innovation" and "Business Process Innovation". Furthermore, based on OSLO Manual, "Innovative Activities" include all Development, organizational, financing and commercialization operations leading to the implementation of product or process innovation. Based on the above rationale, "an innovative company or institution "is a company that produced (or capable of producing) product or process innovation during the last two to three years. It is worth noting that innovation product or process should be implemented and generates societal impact. Product innovation should be used by consumers, and process innovation should be applied by a company or institution. Because innovation generally produces new (or significantly improved) products or processes, with different characteristics and better technical or behavioral features, one would expect that innovation will have an accelerating impact on growth and welfare prospects of the society in general, and the economic system in particular. On the other hand, innovation differs from research and development activities in several ways. First, innovation represents a more advanced level of development compared to research activities. It corresponds to the complete cycle of research that begins with basic and applied research, experimental development, prototyping and modeling, and finally with commercialization and marketing. Innovation can be produced however outside the research institutions based on knowledge worker's advanced skills and competences. As such, innovation generates considerable impact on markets of goods and services, and the value added generated within the production activities. It should be noted finally that innovation represents generally a basic feature of the knowledge Economy and society. Based on the above definitions and rationale, innovation is considered an important factor for transforming countries to a knowledge-based economy and achieving socioeconomic sustainable development. (Radwan 2018; Khorshid 2018; EBRD 2019).

1.2. Multi-dimensional Innovation Model

Given its sizable impact on markets of goods and services, the performance of production activities, and the society at large, innovation can be conceptually represented by a multidimensional model. As shown in figure (1), the studies on innovation as well as approaches for estimating its impact are grouped into three categories or dimensions including; i) sources of producing innovation, ii) innovation domains and iii) classes of innovation Outputs (Khorshid 2019). With respect to the "first category", innovation can be generated (or produced) as part of the research and development activities. In principle, the complete research cycle that begins with examination of natural phenomena, carrying out basic and applied research, undertaking experimental development and designing prototype models, ends generally with new commercialized products or new production processes (as an innovation output). This "first innovation producing model" is generally associated with the construction of advanced or modern R&D Infrastructure such as "science and research parks" and "advanced technology valleys", in order to establish the linkages between university research centers and other knowledge producing unites on one hand, and the demand of industries, services and society at large, on the other hand . This first model satisfies also the 4 P's approach of research and development Outputs (namely, Published Papers, Patents, Prototypes and Products), (Khorshid 2015 a). Another source of producing innovation, is the business sector (or commodity producing companies). The outcome of this production category is generally represented by new or significantly improved goods, services, managerial models or marketing methods. The innovation in production activities is analyzed in detail in OSLO manuals. The estimation of innovation inputs, outputs, and efficiency according to this model, is carried out using community statistical surveys. These surveys are broken down into innovative activities, creative linkages (such as sources of information and institutional cooperation), and financial support, as innovation inputs. Innovation outputs are classified as technological and non-technological innovation products, innovation impact, innovation barriers and intellectual property income, (Hollanders et al 2014, European Commission 2017 and ESTIO 2015).

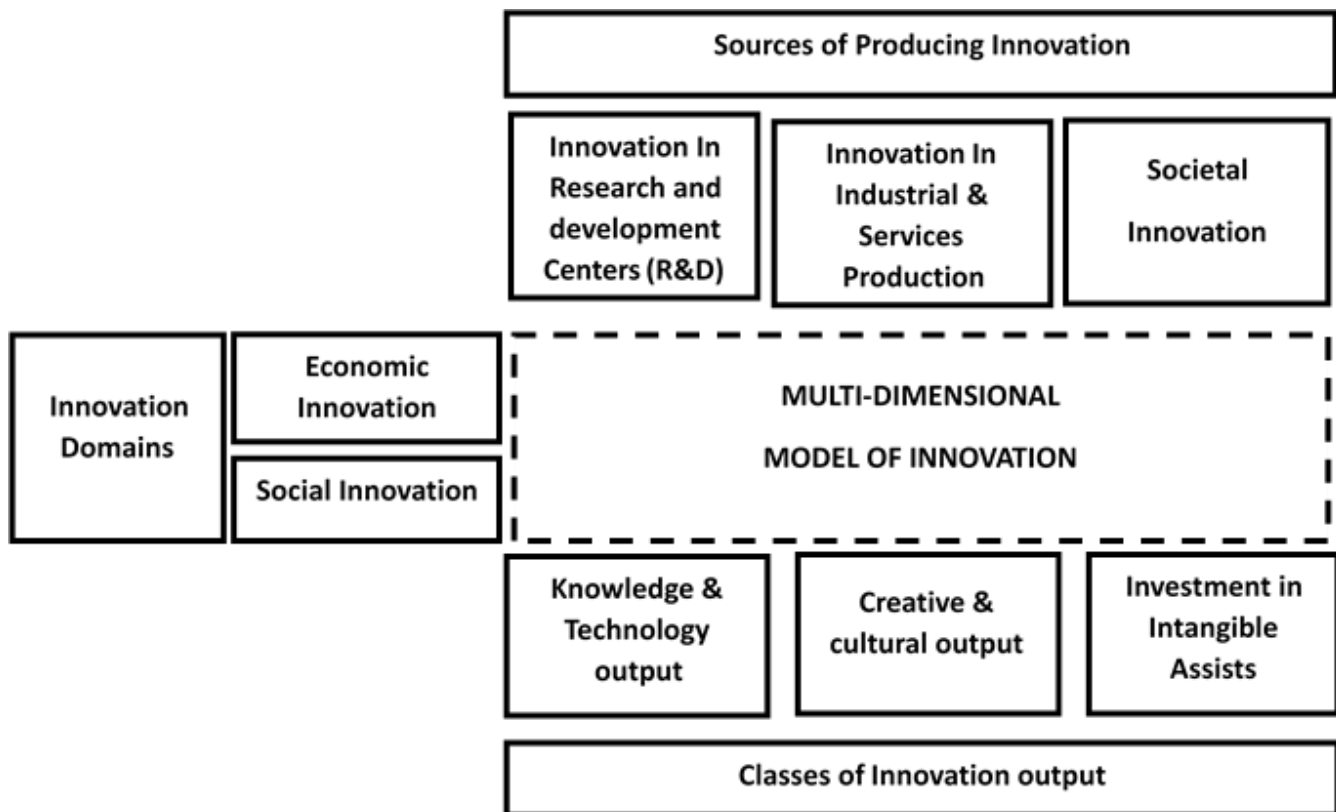
Finally, innovation can be produced, outside the research centers and the production sphere of the economy. This happens generally with societies characterized by creative, highly skilled and educated labor. This innovation model is named as "societal innovation". As a source of producing innovation, this model demands modern and technology advanced environment which coop with the knowledge era and the fourth industrial revolution of the twenty-one century, highly skilled population, and favorable enabling economic and social environment. (UNDP 2016 2017 and Dutta et al 2014). The societal innovation emerged for the first time, as a source of creative products in developing the global innovation index (produced by the world intellectual property income (WIPO), Cornel University, and INSEAD).


Figure (1). Multi-dimensional Innovation Model

Based on this new concept, Innovation Index should reflect a socioeconomic phenomenon explaining scientific, cultural and education levels of the society at large, including skilled and competent knowledge worker, advanced manufacturing technology, and socioeconomic and institutional infrastructural supporting innovation activities. Based on this specific rationale, R&D indicators represent only one input to innovation that should be complemented by education and human capital, physical and computing infrastructures, efficiency of economic markets, effectiveness of business sector and appropriate institutional system to close the circle of innovation inputs. Based on This new vision, innovation outcomes are generally broken down into knowledge and technology outcomes, creative and cultural outputs and intangible assets (Dutta et al 2014).

As shown in figure (1), innovation can be also classified according to its domain of application. In this respect, innovation in economic or social domain is identified. Social innovation is defined by the World Bank as a creative activity directed to address social challenges that cannot be handled by market economies. Given this rationale, social innovation produces new services with the purpose of significantly improving living standards of citizens, as well as their welfare measures. This type of innovation seeks to adopt appropriate policies leading to the integration of labor markets, the creation of new cognitive skills, and the development of new job opportunities. As such, social innovation addresses mainly the social dimension of innovation. On the other hand, innovation in economic domain aims at creating new or significantly improved marketed goods and services in order to enhance productivity and economic growth prospects. Meanwhile, Economic innovation addresses the creativity of production processes and marketing policies. As such, it is considered the corner stone for accelerating the economic development process of a country (World Bank 2007 a,b).

The third "dimension of innovation" is the nature and character of its outcome and impact. Here, we can identify three categories of outputs, knowledge and technology output, creative and cultural output and investment in intangible assets (Cornell University, INSEAD and WIPO 2018). Knowledge and technology outputs are generally classified into knowledge production, impact of knowledge and knowledge dissemination. Knowledge dissemination is represented in the world wide innovation composite indices by a number of variables such as income from property income, high technology exports, ICT exports and foreign direct investments (FDI), especially those directed to knowledge creation and increasing its stock. On the other hand, knowledge impact is assessed by a set of variables such as labor force productivity, intensity of establishing new business enterprises, spending on computer programming, and high technology industrial production. Finally, knowledge creation is generally estimated using number of patents, number of published papers, and number of scientific citations in international journals (Cornell University, INSEAD and WIPO 2018,,Dutta et al 2014, Khorshid 2018). The final innovation output is concerned with "creative and cultural" products. These products relies primarily on creative and knowledgeable human capital that produces new (or significantly improved) ideas, visions, artistic and culture products that can be measured for example by the percent of creative and culture exports to total size of foreign trade, number of artistic films to population size in millions, size of entertainment and advertising markets per thousands of population, and output of printing and publishing industries as a percent of transformation industries (UNDP 2016, 2017 and Khorshid et al 2018).

1.3. Approaches for Estimating Innovation

Despite the important role of research and development (R&D) statistics in drafting national science and technology policies and strategies, they do not represent sufficient conditions for assessing the transformation process of societies to a knowledge Economy. It becomes necessary in the knowledge era, to investigate these statistics in light of their contribution to social and economic development. This process can be ensured by measures related to innovation (figure (2)). Given the multi-dimensional and diversifying nature of innovation activities, the innovation indicators should reflect the modernization of society and its knowledge creation capacity via an integrated research and development system, knowledge intensive high value added industries, creative and cultural products, skilled human capital, enabling socioeconomic and institutional environment, and finally an appropriate physical and computational infrastructure. In figure (2), innovation is globally estimated using two alternative approaches or models. The first approach adopted by UNESCO and OECD organizations, treats innovation process as a production function with input and output indicators. Output indicators of the innovation process is divided into product, process, organizational and marketing innovation. Output statistics include also measures of the resulting impact and different barriers of innovation. Inputs include factors used in the production of innovation output, information in support of innovation as well as institutional cooperation and

financing means. The second approach assumes that innovation is in principle created by educated, skilled, competent and knowledgeable societies. Innovation statistics should coop with this hypothesis by enlarging the scope of their inputs and outputs. On the input front, indicators are grouped under socioeconomic, institutional, physical and information infrastructure (commonly known as enabling environment), in addition to other physical inputs such as research and development, education and training, patent statistics and finance. Outputs include in principle knowledge and technology innovation as well as creative and cultural outcomes. Based on this second approach, a number of worldwide indices are currently developed to estimate innovation inputs, outputs, efficiency and impact. These are the global innovation index (GII) (Cornel University, INSEAD and WIPO 2018), OECD innovation output index (Vertesy and Derss 2016), Innovation union score board (IUS) (Hollanders 2014), and the Asian creativity and productivity index (CPI), (Khorshid 2018).

Figure (2). Approaches for Estimating Innovation

2. Methodology for Estimating the Egyptian Governorate Innovation Index

The Egyptian governorate Innovation composite Index (GICI) hierarchical structure includes 4 levels which are pillars, sub- pillars, sub-indicators and variables. To represent the production sphere of innovation, the composite index is primarily divided into innovation inputs and outputs. The sub-pillar level includes enabling environment

and the factors of production with respect to the input side while the other three sub-pillars represent the output side which are private-sector innovation support, marketing and organisational innovation as well as the societal innovation. Private innovation is directed mainly to citizens (or households) and investors and hence considered as sub-indicators. The remaining level of the composite index is composed of variables to be estimated using surveys and computed data. Each of these pillars, sub-pillars and sub-indicators is constructed in accordance with the standard international methodologies for the developing composite indicators (OECD 2008). In what follows we will explain in some detail the steps used in constructing each of these indicators.

2.1. Conceptual Structure of the Egyptian Governorate Innovation Index

The Egyptian governorate innovation composite index (GICI) is designed to reflect on one hand, multiplicity of purposes, sources of production, alternative domains and extending impact characterizing the innovation process, and to provide on the other hand, appropriate estimates to the components of its production function. The structure of the Egyptian governorate innovation composite index is illustrated in figure (3). As a production process, the composite index is primarily broken down into input and output pillars. The Input pillar is further divided into factors used to produce innovation Outputs, and their enabling environment (sub-pillars). The factors of production sub-pillar include human capital (composed of labor, education level, skills and competences) needed to generate creative processes, goods or services. The estimation of this sub-pillar depends on three sub-indicators related to the number of registered students in Ph.D. and MSc degrees, as well as the graduates of general secondary and vocational schools having advanced grades. These indicators reflect in a way the characteristics of the "knowledge workers" to be involved in the production of innovation products or processes. Another sub-pillar of factors of production is patent statistics. Patent statistics is considered an important innovation input that can be commercialized or marketed in the goods and services markets, if appropriate financing is afforded. According to the structure of innovation inputs, both new established small and medium industries, and advanced technology enterprises are considered also as a support to the creation of the innovation generated within the production activities producing goods and services.

Figure (3) illustrates also the enabling environment as part of the input pillar contributing to the Estimation of the Egyptian governorate innovation composite index (GICI). This sub-pillar is further disaggregated into the cooperation with research centers and universities in order to incubate creative ideas and generate innovation products or processes. Cooperation of research and innovation projects with the outside world, forms also another type of enabling environment. On the output front, the index estimates private innovation output directed to citizens and investors. This innovation support from governorates is done on a personal basis including services to households or private entrepreneurs. The second type of innovation is related to the significant improvements in the organizational structure of companies and their marketing policies. The last type of innovation output is concerned with innovative societies, characterized by creative human capital and advanced technologies, capable of coping with the knowledge era of the twenty-one century. This "societal innovation" is broken down into measures related to significantly improving the green economy and sustainable development, and other efforts directed to significantly modernizing and enhancing governorate's infrastructure.
Figure (3). Conceptual Structure of Egyptian Governorate Innovation Index

2.2 Variables Selection

The selection of the individual variables, included in the construction of each indicator (or sub-indicator), relied on a well-defined clear scientific methodology based on international and local literature. In addition, the concepts and experience from international organisations and agencies in estimating R&D and Innovation activities are employed.

Principal Components Analysis was used to confirm the consistency of the selected variables and their classification into various sub-indicators. These results supported the consistency of the conceptual design in selecting the variables and their classification into various subgroups, in which the explained variance ratio in most cases exceeded 50 per cent (Hair et al 2015). The results of the in-depth correlation analysis and alpha Cronbach coefficient confirmed the validity of the selection and classification of the variables, in which the alpha Cronbach coefficient exceeded 0.70 in most of the cases.

2.3. Data Collection and Organisation

The values of the 17 variables incorporated into the construction of the Egyptian GICI are collected using survey methodology. The survey questionnaire was designed by the Egyptian Science, Technology and Innovation Observatory (ESTIO) of the Egyptian Academy for Scientific Research and Technology (ASRT). The survey was designed and submitted to all governorates based on support from the Ministry of Higher Education and Scientific Research, and the Ministry of Local Development. The number of governorates participated in filing the questionnaire reached 22 governorates (which are Aswan - Port Said - Beheira - Beni Suef - South Sinai - Giza - Dakahlia - Damietta - Sohag - Suez - New Valley - Eastern - North Sinai - Western - Fayoum - Qalyubia - Qena - Kafr El Sheikh - Matrouh - Menoufia - Minya - Red Sea).

For the sake of transparency, simplicity and the possibility of repeating the results, no attempts were made to impute missing values to various variables. The use of the arithmetical mean formula in computing an indicator is equivalent of imputing each of the missing values of the indicator to the mean value of the variable. Data-processing was performed on the assumption that the data were error-free, the team having reviewed it more than once to ensure there were no errors in the data entry. The variables that might lead to a biased indicator value were treated using suitable statistical methods (Groeneveld and Medien 1984). It had been observed that some indicators were linked to other, Size-dependent indicators, such as population. These indicators were therefore rescaled using the size.

2.4. Normalisation and Weighting

The values of variables were normalised in the range [0,100] in which the higher values indicated better results. The rescaling or (maximum – minimum) method was used, in which the maximum and minimum indicate the largest and smallest value of the available indicator values respectively. The normalisation criterion depends on whether the variable is good i.e. has a positive relation with the overall index, or bad i.e. has a negative relation with the overall index. The good indicators are normalised using the following formula:

Normalised indicator value of the governorate = 100 X

$$\left(\frac{\text{raw indicator value of the governorate - raw minimum value of the indicator across governorates}}{\text{raw maximum value of the indicator across governorates - raw minimum value of the indicator across governorates}} \right)$$

In the case of the bad indicators i.e. indicators with an inversely correlated relation, the formula is adjusted as follows:-

Normalised indicator value of the governorate = 100 X

$$\left(\frac{\text{raw maximum value of the indicator across governorates - Raw indicator value of the governorate}}{\text{raw maximum value of the indicator across governorates - raw minimum value of the indicator across governorates}} \right)$$

Different weights are used in the construction of pillars, sub-pillars, sub-indicators and variables of The Egyptian Innovation Index. Equal weights are used in the absence of clear evidence of the diversity of significance of each indicator, as well as in the absence of sound and complete information concerning the existence of causal relationships or a lack of consensus on a classical method for estimating weights. In our case, the design and the disaggregation levels of the innovation index suggest the existence of logical differences , confirmed to some extend by statistical tests and scientific understanding, between the relative importance of sub-pillars, sub-indicators and variable with respect to their impact on the aggregate composite index. Although the pillar level suggests that aggregate inputs and outputs might have equal weights, the breakdown of the sub-pillar level assumes the existence of different weights. For example, we assumed that factors contributing to the production of innovative services of governorate are more important than their enabling environment. Furthermore, factors of production sub-pillar is composed of the two leading inputs to innovation which are the human capital for innovation and patent statistics, whereas the enabling environment in the index is limited to cooperation with research centres and universities and international linkages. Based on this rationale, factors of production sub-pillar is allocated 70 percent weight whereas the enabling environment is assigned 30 percent weight. Within the factors of production human capital for innovation, patent statistics, new established SME industries and technology based projects are assigned the following weights (40,30, 15,15) respectively. Based on the same logic and scientific understanding, the output pillar is decomposed into support to household service and private investors (with 40 percent weight), societal innovative services (composed of the green economy innovation and modernising infrastructure) with 40 percent weight. The remaining weight (20 percent) is allocated to innovation directed to improving marketing methods and enhancing organisational behaviour.

2.5. Index computation

The Egyptian Innovation Capital Index was calculated for 22 Egyptian governorates using the most recent and best available data for the various variables of each governorate. The values of the composite index for the Egyptian Innovation Index were calculated by applying a series of successive aggregations starting with the (more detailed level of) variables and ending by attaining the overall index.

The most well-known aggregations method is the arithmetic (or linear) method. The linear aggregation formula of the sub-indicators (SI_j) to compute the composite index *(CI)* takes the following form:-

$$CI = \sum_{j=1}^{n} w_j \times SI_j$$

Where CI is the proposed composite index to be computed, W_j is the relative weight of the sub-indicator SI_j, n the number of sub-indicators aggregated to form the composite indicator. The arithmetical (or linear) aggregation method is employed to compute all the Egyptian governorate Innovation Composite Index (GICI) pillars, sub-pillars, sup-indicators and Variables in this paper.

3. Analysis and discussion of the Results

The questionnaire was designed and implemented within The auspices of the Egyptian Science, Technology and Innovation Observatory (ESTIO) at the Academy of Scientific Research and Technology (ASRT), and it was submitted to all governorates with support from the Ministry of Higher Education and and state for Scientific Research, and the Ministry of Local Development. As explained previously, the number of governorates participating in the questionnaire reached 22 governorates. Results of applying GICI to the Egyptian governorates are recorded in tables from (1) to (8) and figures from (4) to (8).

3.1 Innovation Performance of Governorates

In tables1,2 and 3, the innovation composite index along with its disaggregated inputs and outputs for each Egyptian governorate are shown. The value of the composite index ranged from 40 percent in case of Kafr El Sheikh governorate to 75 percent for Giza governorate. Giza succeeded to realise the best innovation value of input record (55 percent). This result is the outcome of both the performance of the factors producing innovation, and the enabling environment sub-pillars, which marked 53 percent and 69 percent, respectively. In most of Egypt's governorates, the composite innovation index exceeds 50 percent on the average. Four governorates recorded however an average performance that falls below 50 percent. These are Ben Sweef, Kalioubia, Red Sea and Kafr El Sheikh. Input measures to Egypt's governorate innovation index are generally limited (or having low performance). All governorates except Giza has a mean value less than 50 percent. Giza's performance accounts for 55 percent, whereas other governorates record performance values ranging from 18 percent in case of Matruh governorate to 48 percent in case of New Valley governorate. These results suggest then that the Egyptian government should revise its strategy towards more intensive supporting policies to enhance innovation inputs of governorates. Despite the delimited performance of innovation input sub-pillars, output pillars of most Egyptian governorates generate good results. Based on the outcome from the innovation composite index, the value of output aggregate pillar ranges from 53 percent to around 100 percent. From the 22 governorates, 16 governorates record indicators that exceed 80 percent, 18 governorates produce indicators that exceed 70 percent, and 21 governorates generate indicators that exceed 60 percent. On the other hand, more than 50 percent of the Egyptian governorates generates input performance measure that falls below 30 percent. In general, the deteriorating performance of innovation inputs is associated with the deteriorating measures of the factors of productions (composed mainly of innovative human capital and patent statistics). The set of inputs indicators contributing to the production of innovation output ranged from 6 percent to 53 percent. Furthermore, the performance of Egyptian governorates witnesses a differentiating nature with respect to the measures of the factors of production. On other front, private support to investors and households represents the best output performance measure of the Egyptian governorates. It exceeded other output Variables such as marketing, organisational and societal innovation. Finally, the innovation process of governorates has benefited from the appropriate enabling environment. This enabling environment is reflected in two sub-indicator which are international cooperation, and scientific coordination between governorates, and independent research centres and universities. More than half of the Egyptian governorates marks more than 50 percent with respect to the measured value of the enabling environment.

Table (1). Input and output pillars of the composite innovation index

	Composite Index	Innovation Inputs	Innovation Outputs
Giza	75.30	55.00	95.60
New Valley	70.51	46.89	94.13
Port Said	69.25	38.49	100.00

3.2 Statistical Analysis of Results

In this section, a descriptive analysis is carried out to assesses the statistical parameters (such as the average value, the standard deviation, the maximum and minimum values) associated with the composite index as well as its pillars, sub-pillars and sub-indicators (Tables from 4 to 8 and figures from 4 to 8). The results reveal the following analytical points.

1. The statistics of the Egypt's composite index and its pillars are shown in table(4), whereas the scatter diagram of Governorates are schematised in figure(4). The mean value of the Egyptian governorate innovation composite index is around 61 percent, and the performance of Governorates ranges generally from 44 to 77 percent. This would suggest that the Egyptian governorate innovation performance is on the medium-high level. This result is confirmed by a low standard deviation (representing 1/6 of the mean value), which would suggest the increase of the degree of confidence in the obtained statistics.

2. Figure (4) shows the scatter diagram of the Egyptian composite index for the tested governorates. Despite the existence of some extreme points (such as Kafr-elsheikh and Giza governorates), the value of the composite index of governorates falls generally nearby, or around its average value, which is computed as 60.6 percent.

3. When the innovation composite index is divided into its inputs and outputs (as components of the innovation production function), different analytical results emerge. First, the mean value of innovation Outputs accounts for 87 percent, which is 20 percent higher than the average value of the composite index. The standard deviation of the output pillar is however on the high side (it represents about 62 percent of the mean value). This would certainly reduce the degree of confidence in the positive results of innovation output.

4. Compared to the output pillar, the mean of the innovation input pillar shows a decreasing trend. It does not exceed 35 percent on the average, which represents about half the mean value of the innovation composite index. This result stresses the need of the Egyptian government to adopt more intensive policy packages directed to enhance the innovation inputs in governorates. Furthermore, the scatter diagram of innovation input pillar by governorates (figure (6)) shows that 64 percent of the Egyptian governorates are located below the mean value of the pillar which reaches 34.2 percent. The only exception to this

finding is Giza and the new valley governorates. This result demands also an intensive analytical study to identify the causalities and reasons behind this deteriorating performance.

Table (4). Composite Index statistics – Innovation Inputs and Outputs

Variable	Mean	StDev	Minimum	Maximum
Composite Index	60.58	9.28	43.66	76.78
Innovation Outputs	86.94	53.80	53.80	100.00
Innovation Inputs	34.21	8.53	25.24	57.97
Figure (4) Composite Index Per individual Governorate

5. Table(5) divides the statistical measures pertaining to the innovation output pillar into private innovation support (directed to households and private investors), organisational and marketing innovation measures and societal innovation (broken down into innovation support for green economies and modernisation and development of the governorates infrastructure). The results are generally on the favourable side with a mean value reaching 89 percent, and a standard deviation that does not exceed 21 percent.

6. Given the particular features of the innovation process within governorates, societal innovation should play a more important role in achieving the desired goals. The average value of this sub-pillar is higher than the mean value estimate of the innovation composite index, as well as the innovative support to households and investors. This result coops then with the conceptual innovation rationale.

7. In table (6), the descriptive statistics of the breakdown of the innovation input pillar into sub- pillars are shown (factors of production and enabling environment). The statistical results confirm the deteriorating performance of the factors contributing to the production of innovation output, compared to the enabling environment. The mean value of the factors producing innovation does not exceed 19 percent with a relatively high variance of 12 percent (which represent 60 percent of the mean value). Given this considerable restricted performance, the science and technology policy maker in Egypt should adopt appropriate policy measures directed to enhancing innovation input capacity within governorate. Furthermore, the socioeconomic regional plans and sustainable development strategies need to trace this delimited performance over time. As expected, the enabling environment analytical indicators have shown generally sizeable impact on innovation with a mean value of 68 percent, and standard deviation that is limited to 10 percent.

8. In order to assess the impact of factors of production sub-pillar on Egypt's governorate innovation composite index (GICI), figure (7) decomposes this sub-pillar into its four sub-indicators. The creation of new (or significantly improved) technology-based industries, in support of establishing technology or business incubators and research valleys, has shown reasonable performance with a mean value of 52 percent. This improved performance is meanwhile negatively affected due to the increased standard deviation which represents 62 percent of its mean value. Descriptive statistics show, On the other hand, a clear shortage in providing other factors to generate innovation processes or products (goods and services).

Table (5). Decomposition of innovation output into sub-pillars

Variable	Mean	StDev	Minimum	Maximum
Innovation Outputs	86.94	14.39	53.80	100.00
Private Innovation	83.10	18.17	34.00	100.00
Organizational & Marketing Innovation	91.00	19.54	50.50	100.00
Societal Innovation	88.75	21.23	50.50	100.00
Figure (5). Innovation output Pillar per Governorate

9. The sub-indicator related to the establishment of new (or significantly improved) small and medium size industries reflects in a way, the supporting policies of innovation to the production sphere of the economy. These statistics produce the lowest performance measure which is around 15 percent. Furthermore, its standard deviation exceeded 100 percent of its mean value of performance. Given the growing role of innovation in production activities to achieve economic growth, improve welfare of citizens and satisfy sustainable developed strategies (based on the recommendation of OECD and UNESCO international organisations), appropriate policy measures are strongly needed to address this specific innovation area.

10. Patent statistics is another factor of producing innovation outputs in the Egyptian innovation composite index. Patents are viewed as an important, as well as practical step, towards developing an innovation product or process. A patent application, if properly financed, can produce a new or significantly improved good, service or process that can be commercialised in the economic markets as an innovation outcome. The sub-indicator of patent statistics for innovation in the Egyptian governorate composite index (GICI) generates low performance measures with a mean value of 27 percent and standard deviation of 21 percent (about 78 Percent of the mean value). This law average value with relatively high standard deviation measure stresses the need for intensive policy measures from Egypt's government to support the development and application of patents.

11. Based on international practice and empirical evidence, innovation output cannot be properly produced without skilled, competent and highly educated and trained work force. These knowledge workers are generally needed to form the innovation human capital. Furthermore, human capital development is considered also as a major factor for transforming countries to the knowledge Economy and achieving sustainable development objectives. The collected statistics relevant to the human capital in case of the

Egyptian governorates' innovation index suggest that considerable effort is still needed in this area. Based on the statistical results, the mean value of the human capital measure is only 27 percent, whereas the standard deviation represents 74 percent of this mean value.

12. Table (8) summarises the descriptive statistics of the enabling environment sub-pillar. The enabling environment in the Egyptian governorate innovation composite index is represented by the cooperation with the organisations of the outside world, and the cooperation between the governorate and research centres and universities.

Table (6). Decomposition of innovation inputs into sub-pillars

Variable	Mean	StDev	Minimum	Maximum
Innovation Inputs	34.21	8.53	25.24	57.97
Enabling Environment	68.20	10.36	60.40	95.05
Factor of Production	19.65	11.98	6.09	53.22
Figure (6). Innovation Input Pillar Per Governorate

Table (7). Factors of production sub-pillar and its decomposition

Variable	Mean	SD	Minimum	Maximum
Factor of Production	19.65	11.98	6.09	53.22
Technology Based Industries	52.75	32.32	1.00	100.00
New Small/Med Industries	15.21	17.56	1.00	53.93
Patents for Innovation	24.81	21.00	1.00	100.00
Innovative Human Capital	26.79	19.48	1.00	66.68

Table (8). Decomposition of the Enabling Environment

Variable	Mean	StDev	Minimum	Maximum
Enabling Environment	68.20	10.36	60.40	95.05
Cooperation with Research Center	61.64	14.81	50.50	100.00
International Linkages	83.500	0.000	83.500	83.500

The mean value of the estimated enabling environment ranges from 62 to 83 percent with a standard deviation that does not exceed 17 percent of the mean value of the indicator. In fact, the openness of governorates to cooperation with outside world and their reliance on technical support provided by research centres and university represents a favourable policy measure characterising the knowledge era and contributes to the characteristics of the industrial revolution of the twenty one century.

4. Conclusion and Policy Recommendation

Innovation is becoming today a major factor in support of science and technology policies and the transformation towards knowledge society and economy. Innovation accelerates economic growth and improves welfare measures of citizens as part of the sustainable development strategy of a country.(Alsan 2016, Bassinini et al 2000,, Pessoa 2010, OECD 2004 and 2010, EBRD 2019, Khorshid 2018, Khorshid and Ismail 2019, Ulku 2004). Based on recent worldwide indicators, innovation is considered a prerequisite for transforming countries to knowledge-based technology- advanced digital economy. The innovation process is generally represented by a multidimensional model composed of ; (i) alternative sources (or institution) producing innovation products or processes, (ii) different application domains of innovation and (iii) alternative type of output generated by the innovation process. Innovation can be for example, generated in research centres or universities, developed in manufacturing or services business sectors, created by society at large. On the other hand, innovation can be assessed considering the domain of application (economic versus social domain). Finally, innovation can be developed based on alternative output forms. This classification can include knowledge and technology outputs, creative and culture industries, and intangible assets.

Given its extended worldwide impact on sciences, technology, knowledge and sustainable development , innovation should be estimated on a frequent bases to determine its development stage and extended impact. Innovation statistics need however to consider four development issues; (i) a conceptual design reflecting the analytical objectives of the composite index, (ii) an innovation production function composed of inputs and

outputs, (iii) an enabling environment broken down into socioeconomic, cultural, institutional and physical infrastructure, and finally (vi) advantages, limitations, impact and scope of application.

In this paper, a special composite innovation index is designed, estimated and applied to the Egyptian case. The Egyptian governorate innovation composite index (GICI) is primarily used to assess the innovation performance on the regional or governorate level. It is decomposed into aggregate input and output pillars representing the components of its production function. Inputs include both factors of production and enabling environment (inputs sub-pillars), whereas outputs are broken down into innovation support to households and private investors, marketing and organisational innovation, and societal innovation.

Results of applying the composite innovation index to the Egyptian governorates reveal a number of analytical points and a set of policy recommendations. The performance of governorates measured by the value of the innovation composite index, shows a moderate attitude. The mean of the composite index ranged from 40 percent in Kafr El Sheikh governorate to 75 percent in case of Giza governorate. The mean value of the innovation composite index across governorates is 60.6 percent, and the standard deviation accounts for 9 percent (or 15 percent of the value of the mean statistic). Giza succeeded to achieve the best mean performance with respect to the set of inputs of the innovation production function, which is estimated as 55 percent. This result applies to both the factors of production and the enabling environment (53 and 59 percent respectively). The mean value of the input sub-pillars for other governorates are generally on the low side. Its The mean value across governorates does not exceed 35 percent. Furthermore, their maximum value accounts respectively for only 58 percent, which does not represent an acceptable result. In light of this finding, Egypt's government needs to consolidate efforts towards enhancing the capacity of innovation inputs, with special reference to the components of the innovation production function.

Despite the restricted or delimited results of innovation input sub-pillars, the mean value of the output pillar of most Egyptian governorates generates good statistics. The mean value of the governorates output pillar ranged from 53 to 99 percent on the average. Furthermore, 16 from the 22 governorates generated a mean value of indicator that exceeds 80 percent. It is noted also that innovation support to households and investors represents the highest performance measure of the output pillar. On other front, more than 50 percent of the Egyptian governorates has generated input performance measure that falls below 30 percent. Based on this rationale, the Egyptian government needs to adopt an integrated policy package directed to reduce the difference in performance between governorates on one hand, and achieve the balance between input and output support for all governorates on the other hand.

In principle, the innovation composite index on the regional or the governorate level is characterised by two distinguishing features; the importance of societal innovation statistics, and the emergence of the enabling environment. Science and technology policy makers should in this respect devote particular attention to these two issues in designing the composite index, when moving from the micro level (a company, an organization or a production activity), to a regional or national level. Both the enabling environment and societal innovation in case of the Egyptian governorates, generated mean values ranging from 68 to about 89 percent, with low standard deviation ranging from 10 to 19 percent. This good performance suggests then that the generation process of innovation, and the relative importance of its statistics are considerably affected by the scope of application (a production unit, a service business, an economic sector, a region, or a country at large).

Based on empirical evidence and analytical studies done by UNESCO and OECD organisations, a production activity (producing goods and services) represents an important source of generating innovation products and

processes. In the Egyptian governorate innovation composite index, this dimension is represented in the sub-indicators concerned with the support to advanced technology based industries(composed generally of research parks and business incubators), and the establishment of new small and medium enterprises (SMEs). Although high technology industrial innovation sub- indicator performed properly (with an mean value of 52 percent and a standard deviation of 32 percent), the support to new modern small and medium industries (SMEs) for innovation needs however additional enhancing policy measures from the government of Egypt(the mean value was less than 16 percent and the standard deviation accounted for 17 percent).

The estimated input statistics suggest that the innovative human capital and patent statistics do not receive appropriate support from the government of Egypt. Their measured mean values were 26 and 24 respectively, with relatively high standard deviation of 73 percent and 88 percent of their means, respectively. Given the importance of these factors of production in generating innovation products and processes, further policy measures are still needed in this respect.

It should be noted finally that this paper tried to capture the distribution of innovation efforts, efficiency and effectiveness among the regions (or governorates) of Egypt. The paper suggests that the difference in innovation performance between governorates should be considered as an important factor in developing national science and technology strategies and innovation national plans as well as their economic impact. Up to the authors knowledge, studies concentrating on the analysis of the regional dimension of innovation are up till now, limited to a great extent.

Abstract. Sustainable mining industry contributes to the community well-being and country development. Thus, this research constructs a measurement and model in conducting an empirical study on the corporate social responsibility (CSR) practice and community well-being (CWB) in the mining industry. Accordingly, this study aims to review the structural analysis of CSR and CWB in this particular mining industry. CSR focused on four main dimensions, namely, economic, legal, ethical, and philanthropic. By contrast, CWB is focused on the dimensions of social, economic empowerment, environment, health, service, and facilities. This study also proposes a structural relationship model between CSR practice and CWB in the surrounding mining industry. Research hypotheses were formulated on the basis of the proposed model. This study concludes with a suggested future research.

Keywords: structural equation model, mining industry; corporate social responsibility; sustainable development; community well-being

1.   Introduction

Mining can provide for the welfare of the state and community, but mining activities also have a negative impact on both (Zhao et Al. 2009; Leonard, 2017; Leonard and Lebogang, 2018). Activities result in topsoil erosion, flora destruction, air and water pollution, health difficulties, spoilage of aquatic life species, and social conflict (Kitula, 2005; Corral, Melanie and Earle 2009; Gómez-Álvarez et al., 2011; Gutti et al, 2012; Grozdanovic, Bijelić and Marjanovic, 2018; Katoria et al., 2013). Mining of natural resources requires sustainable management to ensure that society, the economy, and the environment are maintained and conserved (Measham et. al. 2013). The companies in the mining sector can sustainably run in the future if they focus on the role of corporate social responsibility (CSR) on the various dimensions of the people's welfare. Therefore, CSR provides an important role in the process of social development, sustainable development, and community well-being (CWB), mainly of the local communities by considering the expectations of stakeholders (Freeman, 1984; Frynas, 2009; Walton, McCrea and Leonard, 2014); Sarmila et al., 2015) and CSR is able to maintain environmental sustainability and respond positively to the survival of community (Asmeri, Alvionita and Gunardi, 2017).

Previous research has identified the assessment of CSR implementation with various dimensions, such as economic, legal, ethical, and discretionary (Carroll, 1979); economic, social, and environmental (Elkington, 1994); corporate cause promotions, cause-related marketing, corporate social marketing, corporate philanthropy, employee volunteering, and socially responsible business practices (Kotler and Lee, 2005); leadership, vision and values, and stakeholder engagement and marketplace, workforce, supply chain, community, and environmental activities (Researchers from the Ashridge Business School in Danish Commerce and Companies Agency, 2005); economic, social, environmental, stakeholder, and voluntariness (Dahlsrud, 2008). Recent studies that assessed CSR via business excellence models referred to economic, social, environmental, stakeholder, and voluntariness dimensions (Jankalová and Jankal, 2017). CSR dimension has been used to assess the impact of CSR implementations on stakeholders (community, customer, employer, and government) (Ismail, 2009; Lane and Devin, 2018; Rhee, Park, and Petersen, 2018; Phiri, Mantzari and Gleadle, 2019).

As one of the stakeholders, the community requires attention as the recipient of the impact of CSR implementation. Community involvement in CSR practices will help companies build positive perceptions, corporate reputation, trust, and customer loyalty (Deigh, Farquhar, Palazzo, and Siano, 2016). In the case of CSR implementation in the banking Industry, the CSR practice helped enhance overall performance (Narwal, 2007). Similarly, CSR affects financial performance in the European banking industry (Gangi, Mustilli, and Varrone, 2019). In the case of the hotel industry, CSR (responsibility to customers, employees, and society) influences customer behavioral loyalty. Generally, CSR implementation can positively affect the company more than the stakeholder.

Achua and Utume (2015) concluded that CSR impact on the community, from the perspective of the community, was extremely low in all levels. Recent studies from Gaither, Austin, and Schulz (2018) recommended that future research may involve case studies by looking at companies having social and environmental impacts and economic success. Similarly, the study by Hoi, Wu, and Zhang (2018) found CSR activities and the community-level corporate engagement in negative CSR activities. Positive CSR activities enhance a firm's future financial performance. In conclusion, the impact of CSR practice to improve CWB still gains attention in identifying weaknesses and strengths of cases in various countries. Then, the researcher's view is how the CSR dimension can provide a positive impact on the overall dimensions of CWB, such as social, economic, cultural, environmental, and political (McCrea et al., 2014; Walton, McCrea and Leonard, 2014; Lee and Kim, 2015).

In the same context, Arnold (2017) explained that among the initial benefits of CSR is the improvement of the

relationship between companies and communities. Matten and Moon (2008) defined CSR as a policy of action implemented by parties to reflect their responsibility and subsequently advance social interests. Kotler and Lee (2005) believed that CSR improves the people's well-being through the use of company resources. Therefore, each company is expected to create a positive impact on CWB through a CSR program. Murphy (2010) and Hart (1999) stated that CWB is a conceptual framework that incorporates the social, economic, environmental, cultural, and political dimensions identified by individuals and communities. Therefore, the current research aims to form a conceptual model of CSR impact on CWB in the mining industry. The following sections provide the literature review, hypothesis development, proposed research models, conclusions, and future research agenda.

2. Literature Review

The main construct in this research is the company's CSR practice to the community. The company has a legal obligation to socially and economically benefit a community. Accordingly, we adopt "stakeholder theory" because it is rooted in complex business environment relationships (Freeman, 1984, cited in Roberts, 1992, p. 597). This theory explains the nature of the corporation as a legal entity affected by economic and non-economic players with economic and social obligations (Muthuri and Gilbert, 2011). Thereafter, CSR and CWB are explained on the basis of the definition and previous research reports.

2.1 Concept of CSR

CSR can be interpreted as a corporate moral responsibility to the community around the workplace and its operations area. Carroll (1991) defined CSR as economic, legal, ethical, and voluntary aid that organizations provide to a community. Beal (2013) noted that government CSR is a form of commerce that aims to harmonize their values and behaviors against the needs of interested parties, such as users, wholesalers, workers, providers, communities, supervisors, and other interest groups. Dahlsrud (2008) distributed the definition of CSR into five dimensions, namely, environment, social, economic, stakeholder, and volunteer dimensions of philanthropy. In this context, Khoury, Rostami and Turnbull (1999) stated that CSR covers the relationship between government and all stakeholders, such as customers, workers, communities, wholesalers, governments, suppliers, and competitors.

Hopkins (1998) argued that CSR plays a role in morally and responsibly protecting stakeholders to achieve two-sided goals: to retain the benefits of improving the lives of stakeholders within and without the government. Similarly, Basu and Palazzo (2008) defined CSR as a government countermeasure against stakeholders regarding commercial operations and social affairs. The stakeholders include governments, NGOs, and users. In terms of social perspective, Davis and Blomstrom (1975) indicated that CSR should be oriented toward actions taken by a firm to protect and improve social welfare and government interests as well as run the government by maintaining and improving social welfare (Kotler, Saliba, and Wrenn, 1991). The CSR model of Carroll (1991) indicates that CSR comprises four types of social responsibility, namely, economic, legal, ethical, and philanthropic. This model is the most acceptable in measuring corporate responsibility for the implementation of CSR programs (Carroll and Shabana, 2010; Taneja, Taneja, and Gupta, 2011; Carroll and Buchholtz, 2014; Choi and Yu, 2014; El-Garaihy, Mobarak, and Albahussain, 2014; Al-Zyoud, 2017). Table 1 shows the measurement summary of the CSR practice and its dimension.

Table 1. Measurement of CSR Practice and Dimension

2.2. Community Well-being Concepts

Communities comprise people who care about one another, co-exist and interact every day (Flint, Luloff and Finley, 2008). That is, society emerges through social interaction. A community may be based on a place (e.g. warehouse, morgue) or determined by interest (Murphy, 2007). For a society based on a place, welfare is often understood as the physical environment, where the welfare dimension is proven and includes the social dimensions (i.e. psychology, culture and spiritual), economics and nature (Christakopoulou, Dawson and Gari, 2001). The City of Calgary (2010) explained that CWB incorporates the economic, social and physical well-being. Furthermore, Murphy (2010) and Hart (1999) argued that CWB is a conceptual framework that incorporates the social, economic, environmental, cultural and political dimensions identified by individuals and communities. Lee and Kim (2015) also defined CWB as a combination of several domain factors, such as social, economic, cultural, environmental and political. Table 2 shows the measurement summary of CWB.

Services and facilities	
Appearance of built environment infrastructure, including roads	

2.3. Proposed Research Models

A well-implemented CSR is expected to create a positive impact on CWB (Kotler and Lee, 2005) and build stakeholder relationships (Knox, Maklan, and French, 2005). The effects of CSR are measured on the basis of Carroll's pyramid model (1991). In this case, the economic, legal, ethical, and philanthropic dimensions are used to measure the CSR dimensions that have been reported (e.g., Crespo and Del Bosque, 2005; Pérez and Del Bosque, 2013; Ismail, Alias and Mohd Rasdi, 2015). For the CWB dimensions, we relied on collaborations of previous researchers, such as Walton, McCrea, and Leonard (2014); McCrea, Walton, and Leonard (2014); and Kim and Lee (2015). The CWB dimensions are economic empowerment, social, environment, political, health, services, and facilities. Figure 1 presents the proposed conceptual model.

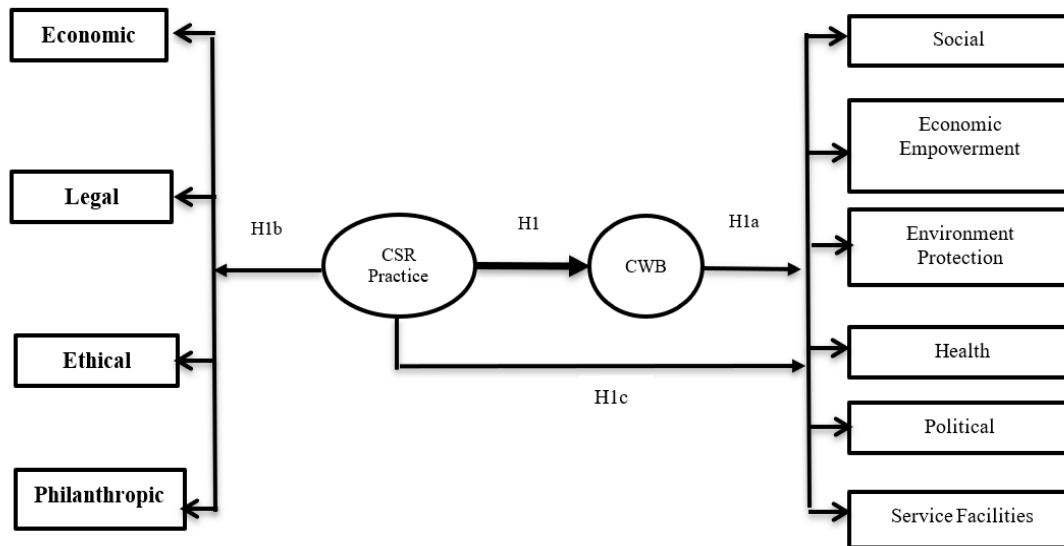
CSR affects community development. Ismail, Alias, and Mohd Rasdi (2015) determined that the majority of CSR-participating corporations had implemented CSR programs from the first decade of the millennium and had their core businesses in diverse sectors. Education-related activities formed the dominant type of CSR contribution. Brew, Junwu, and Addae-Boateng (2015) described CSR activities as related to health, education, community aid, and livelihood. Degie and Kebede (2017) explained that CSR has become an important interface between government and local communities and can be exemplary because it demonstrates that business corporations have the capability to address the pressing needs of communities. Degie and Kebede (2017) also showed that the CSR practice of companies improve the capability of a community and dimension of CWB. Al-Zyoud (2017) indicated that ethical and philanthropic influence in CSR significantly affects sustainability development. Similarly, Sarmila et al. (2015) concluded that a CSR project contributes to the economic welfare of the people through employment opportunities, sources of income, and asset financing. Moreover, Rudito (2014) reported that the CSR practice through community development indicates a positive change in the economic and sustainability aspects. Thus, previous research has shown that direct and indirect CSR practices contribute to CWB. Therefore, the following hypotheses have been developed on the basis of the literature review and research framework:


Figure 1. Proposed model of the study

Note: CSR: Corporate social responsibility
CWB: Community well-being

H1:   A positive and direct significant relationship exists between CSR practice and CWB.
H1a: A positive and significant relationship exists between CWB dimensions (economic empowerment, social, environment, political, health, services, and facilities) and CWB.
H1b: A positive and significant relationship exists between the dimensions (economic, legal, ethical, and philanthropic) and practice of CSR.
H1c: A positive and indirect significant relationship exists between CSR practice and CWB dimensions (economic empowerment, social, environment, political, health, services, and facilities).

3.   Conclusion

The measurement of the CSR dimensions in the adoption of the CSR pyramid is expected to be the standard for companies and contribute to the enhancement of the welfare of society. This measurement is important for the sustainability of the nickel industry of Indonesia and in gaining support from stakeholders, particularly from the community. In the future, the implementation of CSR in the nickel mining companies in Indonesia can improve the CWB. The companies can plan for social, economic, and environmental improvements. This study was also conducted on the basis of the proposed conceptual model, which is a new model based on previous research. In addition, this CSR model analyzes the effects of CSR on CWB and illustrates the contribution of the CSR dimension to CWB. This study is expected to provide a valid and reliable instrument and structural relationship model for CSR practice and CWB. The findings of this study can benefit and contribute to the academe and the industry, particularly to community empowerment practitioners, governments, and NGOs. Generally, the proposed model and research tool can serve as a benchmark and reference source for future research. As a future research agenda, the authors should evaluate the structural relationship between CSR practice and CWB in the Indonesian nickel mining industry.

Appendix - Questionnaire Design

The questionnaire designed for this study used the Likert-type scale of responses. The respondents were asked to rank their answers to 1= strongly disagree to 5= strongly agree.

CSR Dimensions and Item

CSR Dimensions and Item
Economic Responsibility
It is important for each company to perform in a manner consistent with maximizing its profits.
It is important for each company to be committed to being as profitable as possible.
It is important for each company to maintain a strong competitive position.
It is important for each company to maintain a high level of operating efficiency.
It is important that a successful firm be defined as one that is consistently profitable
Legal Responsibility
It is important for each company to perform in a manner consistent with expectations of government and law
It is important for each company to comply with various federal, state, and local regulations
It is important for each company to be a law-abiding corporate citizen.
It is important that a successful firm be defined as one that fulfils its legal obligations.
It is important for each company to provide goods and services that at least meet minimum legal requirements
Ethical Responsibility
It is important for each company to perform in a manner consistent with expectations of societal morale and ethical norms
It is important for each company to recognize and respect new or evolving ethical/moral norms adopted by society.
It is important for each company to prevent ethical norms from being compromised in order to achieve corporate goals.
It is important that good corporate citizenship be defined as doing what is expected morally or ethically
It is important to recognize that corporate integrity and ethical behaviour go beyond mere compliance with laws and regulations.
Philanthropic Responsibility
It is important for each company to perform in a manner consistent with the philanthropic and charitable expectations of society
It is important for each company to assist the arts and cultural activities.
s important that managers and employees to participate in voluntary and charitable activities within their local communities
It is important for each company to provide assistance to private and public educational institutions.
It is important for each company to assist voluntarily those projects that enhance a community's "quality of life".

THE ROLE OF FIRM'S MOBILE APPLICATIONS IN DEVELOPING BRAND'S EQUITY

Mohammad Fahmi Al-Zyoud

Al-Ahliyya Amman University, Business School, Marketing Departement Al-Saro, Al-Salt, Balqa Governorate, Amman, Jordan

E-mail: m.alzyoud@ammanu.edu.jo

Abstract. With the appearance and wide spread of smart phones, individuals have become attached to their mobile phones in order to run their lives, it included texting, calling, calendar, GPS, and appointments. Organizations have exploited the use of smartphones in developing mobile applications in which a user can get the service of the organization and at the same time be exposed to all its marketing and promoting campaigns. Current study aimed at examining the influence of mobile applications on brand equity determinants (Brand Awareness, Perceived Quality, Brand Association and Brand Loyalty) from the perspective of mobile application users in Jordan. Results of study indicated that, mobile applications have a positive influence on brand equity and it managed to be a strong branding platform for marketers in general. In addition to that, results indicated that among the variables of brand equity, brand awareness was the most influenced by smartphones applications. Study recommended to carry out a research that examines the influence of mobile applications on health care performance and how can health care services be eased out for patients who don't have the ability to move from place to another like seniors and handicapped.

Keywords: smartphone applications; brand equity; mobile marketing; brand awareness; perceived quality; brand association; brand loyalty

1. Introduction

The use of cellphones and mobile phones has risen to be a main tool for marketing and promoting for services and goods, hence drawing colossal enthusiasm from both marketers and consumers.According to Masika (2013), mobile phone users presently remain at 6 billion all around the world. Ordinary phones shape the dominant part of these telephones while advanced mobile phones (smart phones) remain at around 1 billion. In this way, cell phones present the best chance of every connected device (Notebooks, desktops, mobile phones, tablets, and ultra-mobile Portable Computers) as an advertising stage. The Mobile telephone shows a few marketing correspondence tool including yet not restricted to Mobile inquiry, Mobile video, Mobile photos and Mobile informing. One road of versatile marketing that has gotten critical consideration is Mobile messaging through the

short message service (SMS) marketing. SMS is an application that enables mobile users to send an instant message of up to 160 characters between cell phones. Sending short messages is likewise regularly known as "messaging" or "content informing". To date, SMS has turned into the most prevalent of every versatile application. In 2010, the quantity of instant messages sent all inclusive achieved 6.1 trillion, or around 600,000 instant messages are sent each second Masika (2013). From the part of business, an ongoing review found that the level of mobile users in European nations who got SMS ad in 2007 moved toward about 100 %.

2. Literature Review

A mobile application – generally referred to as APP – is a computerized software that designed to be used using a smart phone or a tablet. Those applications are normally used in order to get the same service that can be reached through using them on PCs. The idea of mobile application is now becoming more and more apparent given that the number of people using smart phones is increasing on daily bases (King and Raja, 2012).

Lee et al. (2004) argues that a mobile app can be referred to as a software program created for cell phones, for example, cell phones and tablets. They transform cell phones into small-scale powerhouses of capacity and fun. A few gadgets come preloaded with some versatile applications cordiality of their producers or the portable specialist organizations with which they are related (for instance, Verizon, AT&T, T-Mobile, and so on.), yet numerous more applications are accessible through gadget particular application stores (Schierz et al., 2010). Washburn (2011) states that the reasons for these applications run the array, from utility, efficiency, and route to stimulation, games, wellness, and pretty much any others possible. Internet based life is a standout amongst the most prevalent fields of versatile application improvement and reception. Actually, Facebook was the most broadly utilized application in 2017 over all stages.

Numerous online substances have both versatile sites and portable applications (Pavlovaite, and Griesiene, (2019). All in all, the distinction lies in reason: An application is generally littler in scope than a portable site, offers greater intuitiveness, and displays more particular data in a configuration that is simple and natural to use on a cell phone. A versatile application designer makes an application particularly for the working framework in which it will run. For instance, versatile applications for the iPad are bolstered by Apple's iOS, yet not Google's Android. An Apple application cannot keep running on an Android telephone, and the other way around. Frequently, designers make a variant for each; for instance, a versatile application in the Apple Store may have a partner in Google Play (Rubin et al., 2015).

Mobile applications appreciate relatively lasting network also, the capacity to trade data with their own particular backend also, other outsider servers. This paper demonstrates that much of this correspondence does not convey any unmistakable incentive to the application's client: incapacitating it leaves the conveyed application encounter totally unblemished. However, this secretive correspondence accompanies costs, for example, potential security breaks, transfer speed charges, control utilization on the gadget, and the unsuspected nearness of proceeded with correspondence between the gadget and remote associations. Truth be told, we saw that a few prevalent applications, e.g., Walmart and Twitter, produce administrations that secretively speak with remote servers even at the point when the application itself is latent and the client is unconscious that the brought forth benefits are running out of sight (Priyantha et al., 2001). According to Florido-Benítez and Martínez (2015), mobile applications are by and large progressively utilized in cell phones and tablets to get to news, amusements, excitement, climate and other data. Extensive airplane terminals are exploiting the solidification of cell phones in the 21st century to make applications for marking and correspondence. These applications have prompted the production of another promoting outlet, portable marketing, that can be utilized as a business specialized instrument. Over the most recent couple of years, this advertising model has united itself into an item as opposed to a simple correspondence instrument because of its multi usefulness, which contributes increased the value of the substance of the administrations advertised. Portable marketing likewise adds to larger amounts of fulfillment

among airplane terminal customers. In any case, for versatile marketing foundation to make long haul progress, it must give advantages to air terminals and carriers through the portable applications. New data innovations made new media – cell phones, by which can be applied mobile marketing. In his paper, Joshi (2013) distinguishes cell phones as a critical development whose effect on the organization most likely will not stop soon. To accentuate their significance and vital part in business, Joshi (2013) calls cell phones "vital development". Since cell phones are in every case near their proprietors, they make enthusiastic effect. Dushinski (2009) in his paper characterizes mobile marketing as a progressive device for associating organizations with every one of their customers through their cell phones in the ideal time, on a correct place and with proper direct message. Becker and Arnold (2010) stress meaning of mobile marketing which have been given from Mobile Marketing Association, which says that mobile marketing is an arrangement of methods that empowers correspondence with organizations target gathering of people on intuitive and applicable way through cell phones. Likewise, mobile marketing is another marketing channel, which has been made amid the advancement of online business. In spite of the fact that it is conceivable to connect target bunches by means of cell phones, Tanakinjal et al. (2011) express that it is critical to attempt and investigate the conceivable outcomes to influence it to work. As indicated by Andrews et al. (2012), portable promoting is any type of marketing correspondence that has been utilizing cell phones amid the making of potential chances and advantages for clients, what incorporates area based versatile administrations and administrations for the conveyance of portable substance. Advertising specialists concur with the way that exercises that have been going ahead with the cell phones, in the most recent decade, had a huge influence on mobile marketing and on plan for buy of potential clients later on (Chinomona I Sandada, 2013). The same number of individuals compare the term of advertising with advancement, it likewise occurs with the term of portable marketing and versatile advancement, what is without a doubt off-base. Tanakinjal et al. (2011) clarify the distinction between these two terms. Versatile marketing is a driver and an establishment for the trading of substance and direct reaction, while portable promoting is type of a message, which has been sent by means of cell phone. Mobile marketing is a type of correspondence with existing and potential customers. Premise of this correspondence has been improvement of media transmission, data and remote advancements. Mobile marketing does not lose the feeling of advertising but rather mirrors the inventiveness of marketing experts and their technique while result ought to be subjective and fruitful advertising correspondence between the organization and clients. Henceforth, versatile advancement is a piece of portable marketing and is one of its most critical exercises. Cell phones are claimed by one individual what empowers correspondence with a particular individual and message that has been sent to them is promptly accessible Hazlett (2011). Likewise, connection with the customers can be entirely unexpected for every customer, what is not the situation in different sorts of advertising (Dushinski, 2009). Due to the open doors given by versatile marketing, organizations can without much of a stretch incorporate into the trading of data with existing and potential clients, with the point of enhancing items. Organizations are progressively settling on portable promoting in view of the pattern and its hopeful projections (Smith, 2010).

Brand Equity

Brand equity is one of the most important aspects in marketing management. The term brand equity was brought into light by Farguhar (1989) who stated that brand equity has the ability to bring about an added value to the product. Keller (1993, p. 1) defined brand equity as *"the differential effect of brand knowledge on consumer response to the marketing of the brand",* Pullig (2008, p.1) on the other hand defined brand equity as *"the value of the brand in the market place".* Also, Severi and Ling (2013, p.125) defined brand equity as *"the marketing and financial values linked with a brand's strength in the market, including actual proprietary brand assets, brand name awareness, brand loyalty, perceived brand quality, and brand associations".*

According to Severi and Ling (2013) high brand value, a brand with high appreciations and acceptance, it implies that the brand can make a type of positive differential reaction in the commercial center. This can imply that your image is effortlessly conspicuous when experienced in promoting or seen on a yard sign. It can imply that your

image is one of the initial ones reviewed when a pertinent incite is utilized – "who might I call to talk about posting my home?" It could imply that people would pay a superior cost for your brand's putting forth. On account of a land exchange, people would pay a standard commission and feel as though they got an important great administration from an outstanding and confided in mark. It could imply that when somebody requests a referral, your image is the first that is prescribed to others. These are certain reactions to the brand – a promptly conspicuous brand, a brand that is reviewed rapidly and effortlessly when required, one that people will pay a top notch cost to gain, and a brand that is prescribed to others. These are on the whole attributes of a high value mark (Simon and Sullivan, 1993).On the other hand, Wood (2000) states that an attempt to characterize the connection amongst clients and brands created the term ``brand equity'' in the advertising literature. The idea of brand equity has been discussed both in the literature related to branding and marketing, and has featured the significance of having a long haul center inside brand management. Despite the fact that there have been critical moves by organizations to be key in how marks are dealt with, an absence of normal wording and theory inside and between disciplines perseveres and may impede correspondence. Brand equity, similar to the ideas of brand and included value has multiplied into different implications. Researchers have a tendency to characterize brand equity uniquely in contrast to advertisers, with the idea being characterized both as far as the connection amongst client and brand (customer arranged definitions), or as something that accumulates to the brand proprietor (organization situated definitions). Severi and Ling (2013) improves the assortment of methodologies, by giving an order of the distinctive implications of brand equity as: the aggregate estimation of a brand as a detachable resource when it is sold, or included on an accounting report; a proportion of the quality of customers' connection to a brand; a portrayal of the affiliations and convictions the buyer has about the brand. Piaralal and Mei (2015) noted that the term brand equity id constructed from multiple dimensions, which forms its meaning and influence. Those dimensions are:

Brand Awareness
According to Severi and Ling (2013, p.126) brand awareness is one of the most important dimensions of brand equity, and it refers to the *"durability of the brand that embedded in the customer memory"*.Djerv and Malla (2012, p.9) stated that brand awareness is the *"brand's ability to be recognized or recalled as a member of a certain product category or service"*. It is believed, that brand awareness plays a significant role in the process of decision making process within the clients due to the fact that it helps the brand being remembered in the mindset of the client specifically if they were the type of people who build their purchase decision based on brand, also it helps in forming the strength of the brand leading to greater loyalty and association (Awan and Rehman, 2014; Piaralal and Mei, 2015; Hashem, 2016).

Perceived Quality
The perceived quality is the element that determents the brand equity as appeared by Severi and Ling (2013). The authors defined perceived quality as *"the overall perception of customers about brilliance and quality of products or services in comparing with the rivalry offering"* (p.127). It is worth to mention here that the perceived quality differs from the quality of the product; perceived quality refers to the customer's emotional evaluation of the product, which can be unfair to use as a general evaluation of the product itself given that the emotional evaluation differs from a customer to another. In addition to that, perceived quality is considered to be a key factor in influencing the customer's decision-making process to purchase (Sprosen, 2014).

Brand Association
Low and Lamb (2000) defined brand association as the memorable characteristics, specifications and ideas that are memorable in the customers' mindset. Brand association can also refer to the set of items, description that makes the brand memorable for others (Gordon et al., 2016; French and Smith, 2013).

Brand Loyalty

This dimension is the core of the concept of brand equity as stated by Djerv and Malla (2012). If the customers buy the item just for its price, features or convenience, and without any interest in the name of the brand then the equity is very weak. On the other hand, if the customer buys a product for the brand, which – from customers' perspective – guarantees for them quality, convenience, good features and suitable prices then the equity is high. Generally speaking, customers who do not get what they paid for are usually customers without loyalty for the brand, and they are welling to change their mindset into another brand. In the case of loyalty, the prior experience of a customer is a must, a customer cannot be considered loyal or not if they haven't had the needed prior experience of the brand (Piaralal and Mei, 2015).

Aims

From the above argument, it can be seen that using mobile phones in marketing has become a main tool for marketers and organization launching from the fact that individuals are becoming attached to their mobiles. They manage a lot of stuff using mobiles this includes emails, calendars, appointments, games, texting and GPS. From that point, marketers have exploited that idea of being attached to mobiles and has worked on making it the main and most important marketing platforms on which a marketer guarantees the receiving of the marketing initiative to the users. With the wide spread use of smart phones, and the appearance of mobile applications marketers have also benefited from this concept through building an application that is able to give the service to the clients along with the marketing process. Many large corporations now have its own mobile application which using it from the client is almost as effective as visiting the organization itself or one of its service booths. That way, clients find that this process saves them time and efforts and at the same time increases the percentage of users and opens the gates wider for potential clients. Launching from a study by (Masika, 2013; Sprosen, 2014; Vikström and Zheng, 2013; Tetere, 2011) this study aimed at examining the influence of using mobile application in increasing the brand equity from the perspective of mobile applications users in Jordan.

Based on the aim above, current study determined on answering the following questions: How can mobile applications help in developing brand equity?

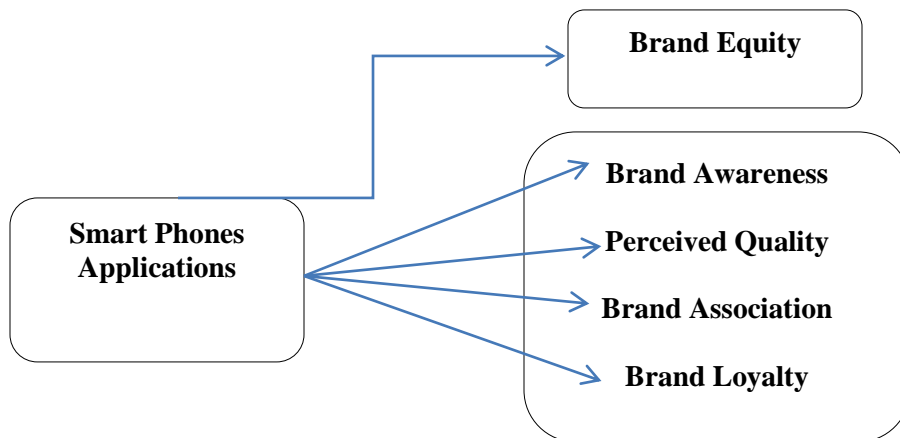
In order to answer the above questions, following model was built so as to determine the main hypotheses of study (Figure 1):


Figure 1. Study Model (Gunawardane et al., 2016; Masika, 2013; Trillo, 2017)

Based on the presented model above, the hypotheses of study will be the following:

Main Hypothesis:

H$_1$: Mobile applications have a statistically significant influence on brand equity from the perspective of smartphones users in Jordan

Sub-Hypotheses:

H$_{1a}$: Mobile applications have a statistically significant influence on brand awareness from the perspective of smartphones users in Jordan

H$_{1b}$: Mobile applications have a statistically significant influence on perceived quality from the perspective of smartphones users in Jordan

H$_{1c}$: Mobile applications have a statistically significant influence on brand association from the perspective of smartphones users in Jordan

H$_{1d}$: Mobile applications have a statistically significant influence on brand loyalty from the perspective of smartphones users in Jordan

2. Methods

Methodological Approach

In order to answer study questions and process the hypotheses of current study the author has chosen the quantitative approach. This approach gives a chance to researchers to apply their study on large numbers of individuals in order to get more dependable results which cover a large number of participants.

Tool of Study

The researcher developed a self-administered questionnaire which was distributed on the study sample in order to collect data. The questionnaire consisted of two main parts, the first took into perspective the demographic variables including (gender, age, education) while the other part consisted to statements regarding the study variables of brand equity and mobile applications in smartphones.

Population and Sample

The population of the study was formed of Jordanian consumers who use smartphones applications. The initial sample consisted of (700) individuals from malls, retail stores and commercial complexes in the Jordanian capital, Amman. The researcher was able to retrieve (520) properly filled questionnaires for analysis. The response rate of current study reached 74.2% which is a statistically approved rate.

3. Results

The empirical data obtained in the process of the research is explained in this section, figures, tables, graphs are used to facilitate such. In this results section we will examine demographic, sample, questionnaire analysis, hypothesis testing, and reliability testing.

Demographic Analysis

Table 1. Sample characteristics according to gender

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Male	285	54.8	54.8	54.8
	Female	235	45.2	45.2	100.0
	Total	520	100.0	100.0	

Table (1) highlighted the sample characteristics according to gender. It appeared through the analysis that 54.8% of individuals were males, while 45.2% of individuals appeared to be females. This indicates that males are into using mobile applications compared to females.

Table 2. Sample characteristics according to age

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	18-22	79	15.2	15.2	15.2
	23-27	193	37.1	37.1	52.3
	28-32	161	31.0	31.0	83.3
	+33	87	16.7	16.7	100.0
	Total	520	100.0	100.0	

Table (2) presented the sample characteristics according to age. From the analysis, it appeared that the majority of the sample 37.1% was from the age range of (23-27) years old.In the 2nd rank came individuals within the age range of 28-32 years old forming 31% of the total sample.

Table 3. Sample characteristics according to education

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	BA	48	9.2	9.2	9.2
	MA	352	67.7	67.7	76.9
	PhD	120	23.1	23.1	100.0
	Total	520	100.0	100.0	

Table (3) presented the sample characteristics according to education. It appeared that the majority if the sample 67.7% held master degree compared to 23.1% who held PhD degree.

Table 4. Sample characteristics according to income

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	250-500	114	21.9	21.9	21.9
	501-750	84	16.2	16.2	38.1
	751-1000	79	15.2	15.2	53.3
	1001-1250	111	21.3	21.3	74.6
	1251+	132	25.4	25.4	100.0
	Total	520	100.0	100.0	

Table (4) above described sample characteristics according to income, from the analysis, it appeared that the majority of the sample (25.4%) had an income range of +1251 JOD which is explained through the fact that most brands which builds its own applications are mostly above average when it comes to price.

Questionnaire Analysis

Table 5. Descriptive Statistics

	N	Minimum	Maximum	Mean	Std. Deviation
Smartphones Applications					
Smartphones application interacts with consumers and present the best service for them	520	1.0	5.0	3.877	.8846
Using my phone to get a service is much easier than visiting the company branch	520	1.0	5.0	3.860	.8918
I prefer using the brand app specially if it works offline	520	1.0	5.0	3.667	1.0978
I know about the promotions and adds from the app not the main website of the brand	520	1.0	5.0	3.727	.9847
I always depend on the application on my phone to know the latest promotions	520	1.0	5.0	3.569	1.0177
I have applications to all my favorite brands on my phone	520	1.0	5.0	3.567	.9472
Applications information don't match reality	520	1.0	5.0	3.600	1.0075
Brand Equity					
Brand Awareness					
I always follow my favorite brand on its application	520	1.0	5.0	3.573	1.0079
Weak brands don't have mobile application	520	1.0	5.0	3.458	1.0360
When there is an application I assume it is a powerful brand	520	1.0	5.0	3.540	.9866
I know the application of a certain brand as soon as I see its logo	520	1.0	5.0	3.508	.9696
Perceived Quality					
Good brands always have applications	520	1.0	5.0	3.617	.9545

I know the level of the brand from the number of individuals who downloaded the app	520	1.0	5.0	3.627	.9573
If the app works properly then the brand is the best	520	1.0	5.0	3.406	1.0042
Cheap brands can't afford mobile apps	520	1.0	5.0	3.517	.9755
Brand Association					
I get all the service I need from the application which makes me appreciate the brand more	520	1.0	5.0	3.519	.9969
All information I need are always on the app	520	1.0	5.0	3.048	1.1874
The application is always updated and gives me the latest promotions	520	1.0	5.0	3.062	1.2798
Most of the information I can get from the brand company can be attained through the application	520	1.0	5.0	3.069	1.1609
Brand Loyalty					
I prefer to stick to a certain brand as long as it has application	520	1.0	5.0	3.071	1.1108
I don't switch my brand if the application is helpful	520	1.0	5.0	3.050	1.4079
I prefer brands with mobile apps	519	1.0	5.0	3.318	.9751
Mobile apps are much easier	519	1.0	5.0	3.351	.9944
Valid N (listwise)	519				

According to table (5), it was seen that all of the questionnaire statements were positively received by the sample which was noted through their answers on the scale. The means of the statements scored higher than 3.00, which were seen to be a good indicator. This gives an indication that the sample individuals had a positive attitude towards statements of the questionnaire referring to the variables as positively received.

Table 6. Descriptive Statistics of Variables

	N	Minimum	Maximum	Mean	Std. Deviation
Smartphone applications	520	1.29	5.00	3.6953	.77397
Brand Awareness	520	1.00	5.00	3.5197	.84390
Brand Quality	520	1.00	5.00	3.5418	.82926
Brand Association	520	1.00	5.00	3.1745	.97027
Brand Loyalty	520	1.00	5.00	3.1952	.88139
Brand Equity	520	1.13	5.00	3.3584	.77014

It appeared from table (6) above that sample individuals had positive attitude toward variables of study. It is shown in the table that all variables scored higher than 3.00 as a mean, which a statistically accepted results and a good indicator of positive attitudes.

Reliability Test:

Through employing Cronbachs' alpha, a reliability test was carried out. Results of the reliability test indicated that all of the items scored higher than the value of (0.60) and they all have given the value of (0.953). This refers to the tool consistency of the study.

Hypotheses Testing

Main Hypothesis Testing (see Tables 7, 8, 9):
- ❖ **H$_1$**: Mobile applications have a statistically significant influence on brand equity from the perspective of smartphones users in Jordan

Table 7. Model Summary H1

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.758[a]	.575	.574	.50267

Table 8. ANOVA[a] H1

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	176.945	1	176.945	700.290	.000[b]
	Residual	130.885	518	.253		
	Total	307.829	519			

Table 9. Coefficients[a] H1

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.571	.108		5.302	.000
	smart	.754	.029	.758	26.463	.000

The main hypothesis (H1) was tested through multiple regression. Results indicated that R value reached (0.758) and the variables are correlated. With a T value of 26.463 at level 0.05 it can be said that results approved the influence of smartphones applications on brand equity.

Sub-Hypotheses Testing (see Tables 10, 11, 12)*:*
- ❖ **H$_{1a}$**: Mobile applications have a statistically significant influence on brand awareness from the perspective of smartphones users in Jordan

Table 10. Model Summary H$_{1a}$

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.789[a]	.622	.621	.51948

Table 11. ANOVA[a] H[1a]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	229.821	1	229.821	851.616	.000[b]
	Residual	139.790	518	.270		
	Total	369.610	519			

Table 12. Coefficients[a] H[1a]

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.343	.111		3.080	.002
	smart	.860	.029	.789	29.182	.000

Looking at tables (10, 11, and 12) it can be seen that the 1st sub-hypothesis was tested through multiple regression. From the analysis it appeared that R value scored 0.789 and both variables were strongly correlated. In addition to that, the T value scored 29.182 at level 0.05 which accepts the hypothesis that smartphone applications positively influence brand awareness.

❖ **H[1b]**: Mobile applications have a statistically significant influence on perceived quality from the perspective of smartphones users in Jordan

Table 13. Model Summary H[1b]

Model Summary				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.684[a]	.468	.467	.60519

Table 14. ANOVA[a] H[1b]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	167.184	1	167.184	456.471	.000[b]
	Residual	189.719	518	.366		
	Total	356.903	519			

Table 15. Coefficients[a] H[1b]

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.832	.130		6.421	.000
	smart	.733	.034	.684	21.365	.000

From testing hypothesis 1b, it can be seen that multiple regression scored an R value of 0.684 confirming the correlation between the variables. With a T value of 21.365 on level 0.05 it can be said that smartphones applications positively influences perceived quality of the brand (Tables 13, 14, 15).

❖ **H$_{1c}$**: Mobile applications have a statistically significant influence on brand association from the perspective of smartphones users in Jordan

Table 16. Model Summary H$_{1c}$

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.618[a]	.382	.381	.76326

Table 17. ANOVA[a] H$_{1c}$

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	186.828	1	186.828	320.696	.000[b]
	Residual	301.772	518	.583		
	Total	488.600	519			

Table 18. Coefficients[a] H$_{1c}$

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.310	.163		1.896	.058
	smart	.775	.043	.618	17.908	.000

In tables (16, 17, 18) it appeared that through multiple regression the hypothesis scored an R value of 0.618 which confirmed the correlation of the variables. In addition to that, a value of T appeared to be 17.908 at level 0.05 which accepted the hypothesis indicating the existence of a positive influence of smartphone applications on brand association.

❖ **H$_{1d}$**: Mobile applications have a statistically significant influence on brand loyalty from the perspective of smartphones users in Jordan

Table 19. Model Summary H$_{1d}$

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.569[a]	.324	.323	.72543

Table 20. ANOVA[a] H$_{1d}$

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	130.592	1	130.592	248.158	.000[b]
	Residual	272.596	518	.526		
	Total	403.188	519			

Table 21. Coefficients[a] H[1d]

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.800	.155		5.152	.000
	smart	.648	.041	.569	15.753	.000

The last hypothesis was tested through multiple regression and scored an R value of 0.569. Also, the T value appeared to be 15.753 on level 0.05 which confirmed the correlation between the two variables and accepted the fact that smartphone applications positively influence brand loyalty.

4. Discussion

After reviewing results of study data analysis, the findings can be summed up as following:
1- Males appeared to be more into engaging in using mobile applications compared to females
2- The majority of sample was from the age range of 23-27 years old
3- The majority of the sample individuals held master degree
4- The majority of sample participants enjoyed the income of more than 1250 JOD which explains their interest in mobile applications and branding
5- The most influences variable of brand equity by mobile applications appeared to be the variable of awareness.

This explains the influence of mobile application in giving higher brand equity to the brand itself through raising the awareness of individuals towards a certain brand.

According to the results above, the researcher was able to answer the question of the study and proved that mobile applications as a marketing tool can be helpful in developing the brand equity among consumers.

Mobile applications have proven its efficiency in increasing the brand equity through the appearance of brand awareness. Results of study indicated that employing mobile applications within the marketing process can help in increasing the awareness of the brand given that the application helps in fixing the brand in the memory of the client leading to higher equity. This idea argued before by Keller (2009) who states that employing mobile marketing can help in generating sales which in its turn can work on the level of awareness. Individuals who have the application and are aware of its usability and speed can also regenerate the brand as it is more stuck to their memory.

When it comes to loyalty, marketing through mobile (mobile marketing) also proved its efficiency in increasing customers' loyalty. For example, tourism and hotel booking applications are proved to be the most efficient in that domain. Many customers are – according to Kim (2011) - present more loyalty to a certain brand when engaging in its application through the web. The use of mobile application in that sense has saved customers time and effort which managed to be welcomed by customers and users.

As for brand loyalty, Kim and Alder (2011) argued that an organization's brand is basically the core of the organization. A brand establishes a name, a logo, an image, and personality. Making the items effortlessly open, offering comfort through helpful applications, and building brand awareness ought to be fused into the advertising

methodology of each organization. Employing mobile applications can offer this and get the customers required with the brand using cell phone applications. Loyalty must begin with the collaboration of the item to the client. As the client turns out to be more aware of the item, the brand's equity develops. The positive, developing picture gives the brand a higher shot of holding the client for future item buys. Another factor for mark faithfulness is the perceptual propensity.

On the other hand, Kaplan and Haenlein (2010) insisted that picking a brand that offers items that are commonplace and agreeable to the purchaser guarantees mark steadfastness. By offering applications that permit check in/out administration, reservations, area benefit at the speed and comfort of a cell phone, permits the neighborliness benefit organizations to manufacture a solid brand association. It has been conjectured that utilizing versatile inn applications will have a constructive outcome all through the brand mindfulness, client commitment and brand responsibility, which thusly decidedly impacts the brand dependability.

5. Conclusion

Current study aimed at examining the influence of mobile application marketing on brand equity and how can an organization develop its brand equity and its variables (Brand Awareness, Perceived Quality, Brand Association and Brand Loyalty) through the employing of mobile applications as a marketing tool.

Sample of the study consisted of (520) consumers from different malls, retail stores and commercial complexes in Jordan. A self-administered questionnaire was distributed on the sample in order to gather data.

From the above mentioned results, it can be seen that there is a positive relationship between mobile application marketing and brand equity development. The use of friendly, useful and easy application can help in increasing the brand equity through focusing on the main variables including brand awareness, perceived quality, brand association and brand loyalty. The nature and characteristics of the mobile application can either attract or alienate individuals from a certain brand; this can be attributed to the technological developments which have opened the gate for brands to try their chance to be popular and widely accepted. Nowadays, customers can help in building brand equity, it not the responsibility of the organization anymore. This is read through the literature which proves that there are many practices and activities within the internet that enable the customer to build a virtual experience of the brand without even trying it; this is called the Word of Mouth – WOM – through exchanging reviews, point f vies and experiences about a certain brand; a customer may be able to form some sort of feeling towards it, those feelings might be either positive of negative.

Understanding the power of mobile application is connected to how smart the organizations are. Building an application that can match the taste of each and every individuals is not that easy. It needs a lot of analysis and understanding of customers, how they think, what motive them, and what influence their purchase decision. From that point, the role of building a strong customer relationship management CRM can't be denied, through a well-built CRM and organization may be more eligible to understanding its customers and how to build a mobile application that can math their taste and push them towards behaving in a way that is for the benefit of the brand and its equity.

Based on the reached aim and the answering of the study question, the following is recommended:
1- Carry out a research that examines the influence of mobile applications on health care performance and how can health care services be eased out for patients who do not have the ability to move from place to another like seniors and handicapped.
2- Examine the influence of mobile applications on teenagers purchase power and how can such applications increase the impulsive behavior of buying among teenage individuals in families.

ECO-ORIENTED CULTURE AND FINANCIAL PERFORMANCE: ROLES OF INNOVATION STRATEGY AND ECO-ORIENTED CONTINUOUS IMPROVEMENT IN MANUFACTURING STATE-OWNED ENTERPRISES, INDONESIA

Noorlailie Soewarno [1], Bambang Tjahjadi [2*]

[1,2] *Faculty of Economics and Business, Universitas Airlangga, Surabaya, Indonesia*

E-mails: [1] noorlailie-s@feb.unair.ac.id; [2]bambang.tjahjadi@feb.unair.ac.id (coressponding author)*

Abstract. This study focuses on investigating the mediating effect of innovation strategy and eco-oriented continuous improvement on the relationship between eco-oriented culture and corporate financial performance. This study provides empirical evidence to the resource-based theory stating that a corporate needs to have valuable, rare, inimmitable, and nonsubstitutable resources to remain competitive. Organization culture, innovation and continuous improvement capabilities are considered as the critical resources that must be developed by a corporate to gain competitive advantage. This study is designed as quantitative research using a variance-based or the partial least square structural equation modeling (PLS-SEM). Study on 103 managers of the manufacturing state-owned enterprises (SOEs) in Indonesia reveals that innovation strategy and eco-oriented continuous improvement partially mediate the relationship between EOC and corporate financial performance. This study contribute to provide greater understanding regarding the need to consider eco-orientation within a corporate life. It implies that for boosting the corporate financial performance, a corporate needs to adapt the eco-orientation and understand the mechanism on how eco-oriented culture affects corporate financial performance using innovation strategy and continuous improvements in eco-oriented operation management processes, customer management processes, innovation management processes, as well as regulatory and social processes. A strong eco-oriented culture will lead to beneficial innovations and eco-oriented continuous improvement; hence it has a positive association to financial performance. Many studies have been conducted on how a culture affects financial performance. However, there are still few studies describing the mechanism of how a culture can improve financial performance using innovation strategy and eco-oriented continuous improvement, especially in the context of environmental issues and in a developing country. Focusing on explaining the mediating effect, this study employs a more comprehensive structural model integrating four eco-oriented variables.

Keywords: eco-oriented culture; innovation strategy; eco-oriented continuous; improvement and corporate financial performance

1. Introduction

A growing number of governments around the world are strengthening their environmental laws and regulations because the environment affects economic development as well as the societies' quality of life. In Indonesia, for example, the Government of Indonesia (GOI) protects the environment using both national and regional level regulations to decrease the rate of emissions to 29%–41% by 2030 to meet the international agreements (Alisjahbana and Busc, 2017). Indonesia as an archipelago consisting of more than 17,000 islands and home to about 267 million people is still facing significant environmental problems. It is believed that Indonesia is the world's second-largest contributor of plastic pollutants in the oceans, after China (Indonesia Investment, 2019). In term of forest degradation, Indonesia is the third largest area of tropical forest degradation after Brazil and Congo and has contributed to environmental issues for years. Indonesia has surpassed Brazil as a tropical country with the highest levels of deforestation (Margono et al., 2014). A study by Turubanova et al. (2018) confirmed that given high rates of loss for comparatively low remaining forest area, Indonesia exhibits greater pressure on remnant primary forests than either Brazil or Congo.

Longstanding debates have also been done between protection for environmental sustainability and the production of valuable commodities (McCarthy and Kathryn, 2016). Several studies have examined the relation between economic growth and environmental degradation. A number of empirical papers find evidence of an inverted between pollution levels rise and income rising (Tamazian and Rao, 2010). Many facets of manufacturing business process have importat implications for natural environment. Design of product, selection of raw materials, operation of manufacturing process, delivary of product or service, and availability of reuse and recycle for spent products have been a big issue of environmental degradation (Ahmed et al., 1998; Klassen, 2006).

Management of firms needs to pay more attention on these rapidly growing environmental issues by building organizational culture, developing innovations in products and programs as well as improving environmentally-related business processes. Most post-modern managers are well aware that sustainability is the today's business goal (Kim and Lee, 2012; Soewarno et al., 2018). No doubt, post-modern firms are required to successfully deal with and keep innovating on the environmental issues to gain sustainable competitive advantage. Green innovation becomes strategically important from time to time.

Modern societies changed dramatically compared to the past (Chitsaz et al., 2019). In post-modernism sustainability is meant for everyone. It tries to involve all people, whether quantitative growth or qualitative development supporters, to work for those causes in which their interests overlap. The relativism of sustainability gives many opportunities for cooperation between the sustainable growth and sustainable development supporters, but because of the polarized worldviews few of them can induce real change (Ketola, 2009).

Sustainability is translated into a "triple bottom line" responsibility, with the implication that the assessment of business results should be based not only on economic performance but also on the environmental and social impact as well (Sheth et al., 2011). Sustainable development and sustainability assessment are two issues that have been addressed by academe and practinioners including local government agencies, community members, as well as commercial and industrial planners (Sacirovic et al., 2018; Zhou, et al., 2018). Industrial symbiosis is defined as a collective approach to competitive advantage in which separate industries exchange materials, energy, water and/or by-products, plays an important role in the transition towards sustainable development (Chertow, 2000, Chertow, 2007). Industrial symbiosis resolves resource depletion problems, waste management

and pollution using waste streams to generate more value across industrial actors (Baldassarre et al., 2019; Chertow, 2007).

The research community has also paid increasing attention to the environment as compared to other aspects of sustainability (Ferreira et al., 2016). Until recently, sustainable development was perceived as an essentially environmental issue, concerning the integration of environmental concerns into economic decision-making (Lehtonen, 2004). Wernerfelt (1984) in the Resource-Based View (RBV) stated that a firm is a bundle of resources, and the way that they are combined enables firms to have a competitive advantage among others. Resource-based view (RBV) is a managerial framework used to determine the strategic resources a firm can exploit to achieve sustainable competitive advantage. Business process, strategy and organization culture are also part of resources that firms owned and used for achieving competitive advantage. The RBV concerns that those resources owned by firms must meet valuable, rare, inimitable and nonsubstitutable (VRIN) criteria (Nason and Wiklund, 2018).

The RBV as a theory is inpired by the work of Penrose (1959) arguing that resources are a source of competitive advantage. Hoopes et al. (2003) stated that the resources account for inter-firm performance differences. The RBV argues that the firm should be considered as a bundle of resources which is defined by Wernerfelt (1984) as anything which can provide the firm with a strength or weakness. These resources are also defined by Barney and Arikan (2001) as tangible and intangible assets which are used by the firm to formulate and implement strategies. In order to be a source of competitive advantage the resource should be valuable, rare, difficult to imitate it and no other resource which can substitute it (Nason and Wiklund, 2018).

Many studies have been conducted on the role of culture in relation to financial performance (Ogbonna and Harris, 2000; Melo, 2012; Nazarian et al. 2017; Rottig and Reus, 2018; Zhou et al., 2018). However, there are still few studies that explain the mechanism of how a culture can improve financial performance, especially in the context of environmental issues. Culture is also important in sustainability involvement among firms around the world as found in the study of Coulmont et al. (2018) which stated that firms in countries with high individualism or high masculinity rankings are more likely to affiliate with the UNGC (United Nations Global Compact). UNGC is an organization that align strategies and operations with universal principles on human rights, labour, environment and anti-corrupetion, and take actions that advance societal goals. Study results show that highly individualist societies (IDV) and high masculinity levels countries appear to be more affiliate with the UNGC. Individuals are less preoccupied and with social and environmental issues and have a boarder viewpoint (Cox et al., 2011; Husted, 2005). And masculinity levels have a positive impact on the UNGC affiliation to enhance their corporate image. These motivations are consistent with the values promoted by masculine society, which include competition, power acquisition, and especially recognition (Cetindamar and Husoy, 2007).

In the era of environmental awareness, eco-oriented culture must be the main habit of management and the focus of every strategy. A growing number of business leaders commits to create a better environment of the world by integrating eco-orientation to their corporate culture. Referring to the philosophy of strategy maps by Kaplan and Norton (2004), one of organizational capital owned by a company is its culture. Organizational culture that includes consideration of the environmental impacts in it is called eco-oriented culture (Kim and Lee, 2012). This culture will lead management of the company to formulate and execute their strategies, including innovation strategy.

In the most basic sense, strategy is the primary means for achieving competitive advantage and subsequent superior performance outcomes (Hansen et al., 2006; Olson et al., 2018). Innovation is a main strategic tool in

order to gain a competitive advantage in such complex environments (Akman and Yilmaz, 2008; Kwak et al., 2018). Also, innovation is a basic precondition for long-term success, growth, performance continuance and firms' survival (Akhlagh et al., 2013). Firms should be dedicated to investing in research and development, manufacturing innovative products and achieving substantial performance to be competitive (Karabulut, 2015). As an alternative to the role of innovation in competitive strategy, the value innovation methodology on strategy has been proposed by Kim and Mauborgne (2005, 2017) regarding how to create uncontested market space and making the competition irrelevant. Leavy (2017) explores how the value innovation strategy works in practice and how it has evolved since its introduction.

Innovation strategy that a firm uses to operate its business must be executed in excellent business processes that lead to customer satisfaction and improved financial performance. Mattera and Baena (2015) used the innovation theory in conjunction with the stakeholder theory to analyze a firm's intangible assets enhancement and found that corporate social responsibility (CSR) affects a firm's value-added in Spanish firms. A study by Chuan and Lin (2017) of 115 financial service firms in Taiwan revealed that technology, human and business resources are crucial in developing an e-service capability, and an innovation strategy positively influences organizational performance. Nowadays, as a global society evolves, innovation strategy appears to be an evolutionary process at work, resulting in the progression of organizational philosophies from the industrial-focused production orientation to the human-focused eco-orientation (Miles and Munilla, 1993). Production activity that has an impact on ecological sustainability had been monitored and controled by government to minimize environmental damage. Environmental concerns have thus impacted manufacturing firms' innovation (Wang & Wang, 2019). Hence firms may adopt an eco-orientation as a strategic competitive advantage, for instance eco-oriented corporate culture and eco-oriented continuous improvement which will be investigated in this study.

Each company has differences in integrating environmental aspects into its daily operations, including building an eco-oriented culture, innovating on eco-oriented products for business processes to achieve better financial performance. Porter, Sheehan and Foss (2009) stated that the activity is the smallest unit of a strategy. The integration of the activity-based and resource-based views provides a comprehensive explanation of how a firm creates value. Therefore, innovation strategy must be reflected in the daily activities of the company's internal business processes including eco-oriented continuous improvements in operations management processes, customer management processes and innovation management processes as well as regulatory and social processes.

The objective of this study is to analyze and empirically test the mechanism of how an eco-oriented culture affects financial performance using innovation strategy and eco-oriented continuous improvement. This study uses a more comprehensive model to examine the mediating effects instead of the direct effects among variables and it investigates the issue of eco-orientation which becomes a trend in the world.

The main contribution of this study is to provide empirical evidence and a more comprehensive understanding of activity-based and resource-based views, especially the mechanism of how a culture affects financial performance in the era of environmental awareness. This study also provides evidence on how managers in a developing country perceive the importance of managing environmental issue in their companies. The study also addresses practical implications and suggestions for policy-making either in a company or a government institution.

Based on the previous discussions, this study has three research questions as follows:
RQ1. Does eco-oriented continuous improvement mediate the relationship between innovation strategy and corporate financial performance?

RQ2. Does eco-oriented continuous improvement mediate the relationship between eco-oriented culture and corporate financial performance?

RQ3. Do eco-oriented continuous improvement and innovation strategy mediate the relationship between eco-oriented culture and corporate financial performance?

2. Literature Review and Hypotheses Development

2.1. Eco-oriented Culture, Eco-oriented Continuous Improvement and Corporate Financial Performance
Jabnoun (2001) stated that the success of continuous improvement initiatives is dependent on many factors that include leadership, structure and shared organizational values. Continous improvement not only refers on changes in managerial activities but it also must be followed by improvements in term of knowledge transfer from owner to employee and senior workers (Herlina et al., 2019). It means that corporate culture can be one of the antecedents of continuous improvement. Culture plays a strategic role in business process improvements. Zehir et al. (2011) found that leadership and organizational culture affect business performance outcomes of firms in Istanbul, Turkey. An empirical study on the role of culture by Chatterjee et al. (2018) also confirmed that flexible organizations (predominantly clan and/or adhocracy cultures) have a more supportive learning transfer environment than stable organizations (predominantly market and/or hierarchy cultures). Stone, Joseph, & Blodgett, (2004) indicating that an organization's ability to develop an eco-oriented corporate culture is related to several factors, which are top management emphasis, management risk aversion, rewards and incentives, local community concerns, organizational connectedness, and industry regulatory climate. Meanwhile Kim and Lee, (2012) find that Stakeholder Pressure can influence the adoption of environmental logistics practices (ELP) to build a unique Eco-Oriented Culture. Continuous improvements will have a good impact on financial performance. This is supported by Chen (2018) stating that a better management of supply chain risks has affected corporate financial performance. Eco-oriented continuous improvement in development, sourcing, manufacturing and transportation activities needs one policies to find solutions for company's environmental issues. Furthermore, this improvement will increase company's efficiency and enhance their revenue opportunity (Orsato, 2009). The first hypothesis is based on logically thinking that the organizational culture focusing on eco-orientation will positively drive eco-oriented continuous improvement which will then enhance corporate financial performance. Therefore, the following first hypothesis is proposed:

H_1: Eco-oriented continuous improvement mediates the relationship between eco-oriented culture and corporate financial performance

2.2. Innovation Strategy, Eco-oriented Continuous Improvement, and Corporate Financial Performance
Scholars have provided empirical evidence that innovation strategy determines the success in innovations and continuous performance improvements, and that it will also have a positive impact on financial performance. A study by Yasar et al. (2017) showed a mediating effect of continuous improvement on innovation-financial performance relationship in 384 companies of Turkish manufacturing companies. Karabulut (2015) demonstrated that the innovation strategy of Turkish manufacturing firms leads them to improve their financial performance. Nybakk and Jenssen (2012) also found that innovation strategy enhances financial performance. Chuan and Lin (2017) proved that an innovation strategy positively influences organizational performance of 115 financial service firms in Taiwan. Pogodina et al. (2019) explained that innovation activity increases efficiency in industrial companies which are largely determined by the level of their innovation and marketing potential. However, Nybakk et al. (2011) stated that the model of innovation strategy and climate for innovation accounts for only 16% of the variation in firm performance. It means that innovation strategy becomes an antecedent only if it is moderated or mediated by other factors. Thus, when a company adopts the innovation strategy with the focus of

the environmental aspect, it is proposed that this strategy must be expressed in the daily operations or business processes which must be also continuously improved in order to meet the requirements of changing market. A better adaptation to an eco-oriented market will certainly lead to a better financial performance (Kwon & Lee, 2019). For this reasoning, the following second hypothesis is:

H2: Eco-oriented continuous improvement mediates the relationship between innovation strategy and corporate financial performance.

2.3. Eco-oriented Culture, Innovation Strategy, Eco-oriented Continuous Improvement and Corporate Financial Performance

As previously stated, culture affects innovation. An exploratory study by Kaasa (2017) revealed the effects of different cultural dimensions on different innovation indicators covering many EU countries and neighbouring countries and confirmed that innovation processes are strongly reliant on culture. A study by Rafailidis et al. (2017) on 480 Greek mid-to-high technology and Small and Medium Enterprises confirmed that quality mediates the relationship between cultural ambidexterity and innovation performance. Prim et al. (2017) also proved that cultural dimensions associate with the degree of innovation at the national level.

The linkage between innovation strategy and continuous improvement is reflected in the interview report conducted by Bapst (1994) which stated that the process of innovation development, especially the early part of the development process, must be systematically analyzed and continuously improved to reduce the repeated same mistakes. Moreover, Calantone, et al. (2002) stated that a positive learning climate is beneficial for firms that aspire to stand out through product development, and new product development requires continuous organizational renewal. It can be concluded that to achieve a better firm's performance, managers who adopt innovation strategy need to implement learning activities which reflect the continuous improvements in their organization. Hence, the third hypothesis is formulated based on the following logical thinking. If a company has adopted a strong eco-oriented culture and wants to improve their financial performance, then the company must execute it in their daily operations by implementing innovation strategy and eco-oriented continuous improvement. To test the logical linkage among eco-oriented culture, innovation strategy, eco-oriented continuous improvement and corporate financial performance, the following third hypothesis is proposed:

H3: Eco-oriented continuous improvement and innovation strategy mediate the relationship between eco-oriented culture and corporate financial performance.

3. Research Model

This study has four variables, namely Corporate Financial Performance (CFP) as a dependent variable, Innovation Strategy (IST) and Eco-oriented Continuous Improvement (ECI) as mediating variables, and Eco-oriented Culture (EOC) as an independent variable. The relationship among those variables is presented in a research model in Figure 1.
Fig.1. Research model

3.1. Research setting and sample

This study derived a sample from 200 managers of the SOEs in Indonesia with the status of "perseroan terbatas" or a limited liability company. There are 101 SOEs and the number of the manufacturing subsidiaries is unknown due to limited access. Indonesia was chosen in this study because environmental issues are still a major problem, such as plastic waste, forest fire haze, factory pollution and other issues that require a change in culture and management mindset. The state-owned enterprises (SOEs) were chosen because they play a significant role along with large private conglomerates in the Indonesian economy (see Appendix). However, the study focuses only on the SOEs. Questionnaires with a covering letter describing the objective of the study and confidentiality assurance were distributed to every corporate secretary of the SOEs, with a request to distribute to the managers in the company and the manufacturing subsidiaries. As many as 104 managers participated and returned the questionnaires. Only 1 questionnaire was not properly completed, yielding a total of 103 usable responses. Therefore the effective response rate was 51.5%. Table 1 shows the types of industry and the number of participated managers.

Table 1. Type of Industry and Participated Managers

	Industry	Participated Managers
1.	Heavy equipment	8
2.	Nuclear power	3
3.	Industrial machinery	9
4.	Pharmaceutical	10
5.	Explosives	2
6.	Ship	7
7.	Salt producer	12
8.	Glass producer	13
9.	Fertilizer	11
10.	Fabric manufacturer	13
11.	Steel	12
12.	Cement	3
	TOTAL	**103**

3.2 Analytical Technique

This study employed a variance-based or partial least square (PLS) stuctural equation modeling to test the hypotheses, The PLS was considered suitable for this study for the following reasons. Firstly, it can handle multiple dependent and independent variables simultaneously (Chin, 1998a, 1998b). Secondly, it can deal with small sample sizes and multicollinearity among independent variables (Nitzl, 2016). Thirdly, it does not require a normal distributional assumption (Chin, 1998; Chin and Newsted, 1999).

3.3 Instruments

3.3.1 Corporate Financial Performance

Corporate financial performance is operationally defined as the perception of a manager regarding the four financial perspectives as in the strategy maps created by Kaplan & Norton (2004), namely improve cost structure, increase asset utilization, expand revenue opportunities and enhance customer value. Among those four perspectives, only two perspectives were used to provide the measurements for this indicator, namely increase asset utilization and expanding revenue opportunities for the following reasons. Firstly, Increasing asset utilization closely relates to improving cost structure. This means that when asset utilization increases, then costs will be reduced. Secondly, expanding revenue opportunities also closely relates to enhancing costumer value. This means that customer value will be increased when a company creates more opportunities to sell products to customers. It was measured by using a questionnaire with a 6-point Likert scale which is used to avoid central tendency bias. This concept is regarded as the model which is appropriate for measurement (Chang, 1993). With use of this scale, the respondents cannot choose the moderate value, middle point in this kind of rating scale, the respondents have to consider the answer for a while. Chen, Lee, & Stevenson (1995) found that Japanese and Chinese were more likely to choose the midpoint of a Likert scale item than Americans, but we found this effect only for items involving expression of positive feelings. We made a conclusion that Asians with likely the same cultural collectivism groups as Japan and Chinese, has the same way to respond Likert Scale using mid-point. That is the reason why this research used 6-Point Likert Scale.

3.3.2   Eco-oriented Continuous Improvement

Eco-oriented continuous improvement is operationally defined as the perception of a manager regarding continuous improvement considering eco-orientation during 2015 to 2017. It was measured with a four-item-questionnaire adapted from Lee (2004) using a 6-point Likert scale, but with some modifications to measure the eco-orientation.

3.3.2.1 Innovation Strategy

Innovation strategy is operationally defined as the perception of a manager regarding innovation strategy she/he has formulated during 2015 to 2017. It was measured using a questionnaire adapted from Akman and Yilmaz (2008) with a 6-point Likert scale. This instruments used Venkatraman's typology (1989) which defined innovation strategy as composed of six dimensions, namely aggressiveness, analysis, defensiveness, futurity, proactiveness and riskiness. For this study, only four dimensions were used, excluding aggressiveness and analysis due to practicality reasons. Both aggressiveness and analysis are not used in this study because they do not fit the character of SOEs management which should not act aggressively and tend to be excessively bureaucratic.

3.3.3   Eco-oriented Culture

Eco-oriented culture is operationally defined as the perception of a manager regarding her/his firm's culture which focuses on eco-orientation during the last three years. It was measured with the eco-orientation questionnaire adapted from Stone et al. (2004) using a 6-point Likert scale.

4. Analysis and Results

4.1 Descriptive Statistics

Table 2 presents the results of the descriptive statistics of variables. It shows both theoretical and actual as well as minimum and maximum scores of responses, mean and the standard deviation. Although there is a wide range of responses, the mean values show that the managers tended to have a strong commitment to their corporate financial performance (5.06). They believed that their company implements eco-oriented continuous improvement (5.04) in their daily operations. The less highly rated eco-oriented culture (4.69) and innovation strategy (4.77) reflect that the state-owned enterprises in Indonesia have not yet become concerned with eco-oriented culture and innovation strategy.

Table 2. Results of descriptive statistics

Variable	Theoretical Score		Actual Score		Mean	SD
	Min	Max	Min	Max		
Eco-oriented Culture (EOC)	1	6	3	6	4.69	0.58
Innovation Strategy (IST)	1	6	2	6	4.77	0.95
Eco-oriented Continuous Improvement (ECI)	1	6	3.25	6	5.04	0.66
Corporate Financial Performance (CFP)	1	6	3	6	5.06	0.75

The focus of this study is to empirically prove the relationships among variables studied using a more comprehensive model. Therefore, this study employed a structural equation modeling for analytical method. The research hypotheses were tested using a variance-based application package which is commonly used and is suitable for social research (Hair, Risher, Sarstedt, & Ringle, 2018). The PLS structural equation modeling is a technique which simultaneously examines both measurement and structural models. The measurement model specifies the relationship between the measures and the latent variables or constructs. It also assesses the reliability and validity of measures relating to specific constructs. The structural model identifies the relationships among constructs (Chin, 1998b).

4.2 Measurement model analysis

The objective of the measurement model analysis is to evaluate the relationship between measures and constructs so that the reliability and validity of measures relating to specific constructs can be assessed. Table 2 shows that all measures are significant and above the 0.60 loading level. Chin (1998a, 1998b) stated that loading factors should be at least 0.60 meaning that the measure is accounting for at least 60 percent of the variance of the underlying latent variable. The cut-off point of 0.60 shows that the measures share more variance with their respective constructs than with the error variance. Furthermore, Table 3 shows the composite reliability coefficients for the constructs are all above the accepted level of 0.70 as stated by Nunnaly (1967).

The construct validity consists of convergent validity and discriminant validity. The average variance extracted (AVE) was employed to assess convergent validity in this study. According to Hulland (1999), a construct should have an AVE measure of 0.50 or more to be considered as having adequate convergent validity. Table 3 reveals that the AVEs for all the constructs are above 0.50, and this provides evidence of convergent validity.

Table 3. Results of reliability and convergent validity

Latent Variable	Loading	P Value
Eco-oriented Culture (Composite Reliability = 0.815; AVE = 0.594)		
EOC 1	0.765	<0.001
EOC 2	0.779	<0.001
EOC 3	0.769	<0.001
Innovation Strategy (Composite Reliability = 0.953; AVE = 0.834)		
IST 1	0.906	<0.001
IST 2	0.906	<0.001
IST 3	0.913	<0.001
IST 4	0.929	<0.001
Eco-oriented Continuous Improvement (Composite Reliability = 0.915; AVE = 0.730)		
ECI 1	0.873	<0.001
ECI 2	0.86	<0.001
ECI 3	0.807	<0.001
ECI 4	0.877	<0.001
Corporate Financial Performance (Composite Reliability = 0.913; AVE = 0.840)		
CFP 1	0.917	<0.001
CFP 2	0.917	<0.001

Table 4. Discriminant validity.

	EOC	IST	ECI	CFP
EOC	**0.771**			
IST	0.396***	**0.913**		
ECI	0.365*	0.659***	**0.855**	
CFP	0.365*	0.647***	0.65***	**0.917**

***Significant at $p < 0.01$
*Significant at $p < 0.1$

Discriminant validity in this study is evaluated by comparing the square roots of AVEs with the correlation between constructs to describe whether a construct shares more variance with its measures than with other constructs (Fornell & Larcker, 1981). It is valid when the square root of AVE of a construct is greater than the correlation between the construct with another construct. Table 4 shows correlation among constructs in the off-diagonal and the square root of AVE in the diagonal. Table 4 indicates adequate discriminant validity because the diagonal elements are all greater than their respective off-diagonal elements. In conclusion, it is demonstrated that the measurement model is reliable and valid.

Table 4 also shows positive significant correlations between eco-oriented culture and corporate financial performance (r = 0.365; p<0.1), innovation strategy (r = 0.396; p<0.01); eco-oriented continuous improvement (r = 0.365; p<0.1). These results suggest that eco-oriented culture is an important variable in improving innovation strategy, eco-oriented continuous improvement and corporate financial performance. In addition, there is a positive and significant relationship between innovation strategy and eco-oriented continuous improvement (r = 0.659; p<0.01) indicating that innovation strategy may improve eco-oriented continuous improvement.

4.3 Structural model analysis
The structural model is employed to test the hypotheses of this study. This model test is used to examine if the effect of eco-oriented culture on corporate financial performance is mediated by innovation strategy and eco-oriented continuous improvement. In performing the structural model analysis the following two-step procedures (Baron and Kenny, 1986) were used. Firstly, a test for knowing if the eco-oriented culture affects corporate financial performance was conducted. Secondly, PLS was run for the full model by including innovation strategy and eco-oriented continuous improvement. Table 5 (Panel A) shows that before including mediating variables, eco-oriented culture is positively associated with corporate financial performance (path coefficient = 0.39; p<0.01). This result leads to further analysis by introducing the mediating variables of innovation strategy and eco-oriented continuous improvement.

Table 5 (Panel B and Panel C) shows the following results. First, the relationship between eco-oriented culture and eco-oriented continuous improvement is positive and significant (path coefficient = 0.125; p=0.096<0.1), and the relationship between eco-oriented continuous improvement and corporate financial performance is also positive and significant (path coefficient = 0.406; p<0.001). Therefore, hypothesis 1 stating that eco-oriented continuous improvement mediates the relationship between eco-oriented culture and corporate financial performance is supported (path of indirect effect=0.051; p-value = 0.025<0.05). Secondly, the relationship between innovation strategy and eco-oriented continuous improvement is positive and significant (path coefficient=0.611; p<0.001), and the relationship between eco-oriented continuous improvement and corporate financial performance is also positive and significant (path coefficient =0.406; p<0.001). Therefore, the second hypothesis stating that eco-oriented continuous improvement mediates the relationship between innovation strategy and corporate financial performance is supported. Thirdly, the relationship between eco-oriented culture and innovation strategy is positive and significant (path coefficient=0.412; p<0.001), innovation strategy and eco-oriented continuous improvement is positive and significant (path coefficient=0.125; p=0.096), and the relationship between eco-oriented continuous improvement and corporate financial performance is also significant (path coefficient =0.406; p<0.001). Thus, the third hypothesis stating that eco-oriented continuous improvement and innovation strategy mediate the relationship between eco-oriented culture and corporate financial performance is also supported.

The direct effect of the relationship between eco-oriented culture and corporate performance before including mediating variables shows that the value of β coefficient to be 0.39 with p<0.01. The direct effect of the relationship between eco-oriented culture and corporate performance after including mediating variables shows the smaller value of β coefficient as 0.125 with still significant p=0.097 <0.1. As argued by Baron and Kenny (1986), a full mediation exists if a significant direct effect of the independent variable and dependent variable becomes insignificant after controlling for the effects of the mediating variable. Also, Baron and Kenny (1986) claim that a partial mediation exists if the relationship between the independent variable and dependent variable remains significant after controlling for the effects of the mediating variable. This means that in this study, innovation strategy and eco-oriented continuous improvement partially mediate the relationship between eco-oriented culture and corporate financial performance.

Table 5. PLS results of path coefficients

PANEL A:	β Coefficient	Probability	R² Coefficient of Determination
Before including mediating variables			
Direct Effect			
EOC > CFP	0.39	p<0.01	0.15
PANEL B:	**β Coefficient**	**Probability**	**R² Coefficient of Determination**
After including mediating variables			
Direct Effect			
EOC > CFP	0.125	p<0.1	0.53
EOC > IST	0.412	p<0.001	0.17
EOC > ECI	0.125	p<0.1	0.45
IST > CFP	0.329	p<0.001	0.53
IST > ECI	0.611	p<0.001	0.45
ECI >CFP	0.406	p<0.001	0.53
PANEL C:	**Indirect Effect**	**Probability**	**Decision**
Panel B: Indirect Effects			
EOC > ECI > CFP	0.051	p<0.05**	H_1 is supported
EOC > IST > CFP	0.136	p<0.001***	H_2 is supported
EOC > IST > ECI > CFP	0.102	P<0.05**	H_3 is supported

5. Discussion

When the first hypothesis is supported, it means that this study has provided empirical evidence of the mechanism on how eco-oriented culture affects corporate performance through eco-oriented continuous improvement. The finding of descriptive statistics suggests that managers have a high commitment in achieving a good financial performance. This issue is understood because the company's financial performance greatly affects their financial condition as employees. Furthermore, managers feel the need to make continuous improvements in their business processes, especially in producing environmentally friendly products and Green products which are needed to meet the expectations of consumers who are increasingly concerned about the environmental issues. The low highly rating of eco-oriented culture by managers suggests that the implementation of organizational culture which includes the environmental issues is not strong enough at the SOEs and its subsidiaries in Indonesia. This explains why Indonesia still faces vast environmental problems. It is suggested that the management of the SOEs and its subsidiaries build a strong eco-oriented culture in order to take advantage of the coming of the green consumers era and the threat of eco-oriented competitors. Eco-oriented culture and eco-oriented continuous improvement can be used as the source of competitive advantage to face the global competitors starting to flood the Indonesian market.

The low highly ratings of eco-oriented culture also suggests that managers of the SOEs and subsidiaries in Indonesia have a relatively above-average concern on the importance of eco-oriented culture in relation to eco-oriented continuous improvement and financial performance. They view that culture is important for improving the business processes and the financial success of their company. They realize that having an organizational culture which includes environmental concerns is crucial to building habits in the daily management activities. Although now they don't have a strong eco-oriented culture, managers tend to perceive that culture will drive their company to continuously make improvements in environmentally friendly products and programs in order to achieve financial success. This result concludes the path that the stronger the eco-oriented culture, the better is the eco-oriented continuous improvement, and then the better is the corporate financial performance. This finding supports and extends the results of the previous studies by Jabnoun (2001), Zehir et al. (2011), Chatterjee et al. (2018), and Chen (2018).

The second path to excellent corporate financial performance is to have a good understanding of the mechanism on how innovation strategy affects corporate financial performance through eco-oriented continuous improvement. The moderate rating of innovation strategy reflects that the managers of the SOEs and their subsidiaries in Indonesia have above-average concerns on the importance of innovation as strategy. This finding suggests that managers feel the need for their company to have an innovation strategy as a means to deal with the dynamics of a rapidly changing business environment. Good innovations in environmentally friendly products and programs will guarantee the continuity of the company. The company may become the first mover as the green innovator and enjoy its competitive advantage position. The innovation capability must be continuously executed in the daily business processes, and then it will lead to customer satisfaction and financial success. This finding is in line with the results of the previous studies by Nybakk and Jenssen (2012), Karabulut (2015), and Chuan and Lin (2017).

Finally, the third path to excellent corporate financial performance can be achieved by understanding the mechanism of how to use both innovation strategy and eco-oriented continuous improvement in the relationship between eco-oriented culture and financial performance. As stated by Kaplan and Norton (2004), excellent financial performance needs revenue strategy and cost strategy. Every manager understands that revenue improvements can be achieved through delivering the right value proposition to customers, including eco-awareness or green customers. Then, the managers will align their business processes, especially customer management processes and operation management processes to meet the eco-oriented customers and always continuously make improvements. To generate a good internal business process, the managers need the readiness of human capital, information capital and organization capital (M. Chen, 2005; Kaplan & Norton, 2005). Culture is one strategic element in organization capital that provides a foundation for members of the organization to work with a trusted management philosophy (Posner, Kouzes, & Schmidt, 1985). Without the presence of a strong organizational culture, the company does not have a solid foundation in developing and executing innovation strategies as well as making continuous improvements so that it will be difficult to achieve a good financial performance. The understanding of the third path to excellent corporate financial performance in the era of green stakeholders, including customers and green competitors is crucial for managers, including the managers of the SOEs and their subsidiaries in Indonesia. This result supports and expands the results of previous studies by Bapst (1994); Calantone et al. (2002); Kaasa (2017); Rafailidis et al. (2017); and Prim et al. (2017).

Conclusions

Many previous studies have been conducted to find evidence of the direct impact of organizational culture or strategies or continuous improvement on financial performance (Cox, Friedman, & Tribunella, 2011; Hillestad, Xie, Haugland, & Hillestad, 2010; Posner, Kouzes, & Schmidt, 1985). However, very rarely are studies conducted to seek the mediating effect of innovation strategy and continuous improvement on the culture-financial performance relationship, especially in the context of environmental awareness (eco-orientation) and in a developing country (Soewarno, Tjahjadi, & Fithrianti, 2019).

Using a sample of 103 SOEs managers, this study has provided empirical evidence of the resource-based view (RBV). This study employs a variance-based or partial least squares structural equation modeling to test the hypotheses. The results show the following. Firstly, this study proves that eco-oriented continuous improvement partially mediates the relationship between eco-oriented culture and corporate financial performance. Secondly, this study confirms that eco-oriented continuous improvement partially mediates the relationship between innovation strategy and corporate financial performance. Thirdly, this study also proves that eco-oriented continuous improvement and innovation strategy partially mediate the relationship between eco-oriented culture and corporate financial performance.

This study makes an original contribution in terms of seeking the mediating effects, building a more comprehensive model, focusing on eco-orientation and setting research in a developing country. The results help managers to understand the importance of eco-orientation and awareness in their company and how to use it in achieving a better performance. This implies that managers of the SOEs need to build a strong eco-oriented culture, to develop and execute innovation strategy, to implement that culture and innovation in continuous process improvements, so that it will drive financial performance. This encourages managers to have a more comprehensive and holistic understanding of a value creation process.

This study has the following limitations: Firstly, this research is conducted in Indonesia and uses managers of the SOEs and their subsidiaries as sample, therefore it limits the generalization. To improve the generalization, future research must be conducted in other countries with different cultures and regulations as well as managers in publicly listed companies. Secondly, using questionnaires to obtain data from the managers' perception may raise the issue of cognitive bias. In the future, researchers can use secondary data even though this is also difficult due to the issue of proxies and measurements as well as confidential data gathering. Thirdly, in terms of the analysis method, this study employs a partial least squares (PLS) structural equation modeling. It raises the issue of causality, and therefore a future study could employ other approaches such as experimentation. The model and hypotheses of this study can still be used by future researchers with the addition of other variables such as eco-oriented creativity and legitimacy.

Abstract. Investigating green growth is a continuing scientific concern within academia, governments, and international organizations in recent years. This paper analyzes the discourse on green growth assessment methods. There are three primary aims of this study: 1. To identify factors influencing or stimulating green growth. 2. To analyze sets, frameworks, and indices of green growth indicators designed by international organizations and scientists. 3. To develop the Green Growth evaluation Index and to validate it on the assessment of green growth status of the European Union countries. The methodological approach taken in this study is a mixed methodology based on data analysis, generalization, and index assessment. The study offers important insights into the discourse on green growth evaluation, analyzes green growth measurement tools, and provides the Green Growth Index which can be applied to evaluate green growth in developing and developed countries. Secondary data have been collected from Eurostat, the World Bank databases, and UNDP Human Development Reports for the year 2018. The results show that green growth is uneven in the European countries; the Green Growth Index and all three pillars vary between countries due to the fact that several countries lag behind all the indicators included in the Green Growth Index.

Keywords: green economy; green growth; assessment methods; economic evaluation; green growth index; European Union

1. Introduction

With an emphasis on climate change, interest in green economy and green growth is increasing. It is agreed on the need to replace traditional economic models in a more environmentally friendly manner. Green growth is indicated as one of the ways to replace the existing models. It should be noted that there is used a variety of terms related to green economy (smart economy, sustainable economy, circular economy, low-carbon economy, blue economy, etc.). Besides, the boundaries of each term are not clearly explored (Pieroni et al., 2019). UNEP (2011), Popa et al. (2011), Pahle et al. (2016), He et al. (2019), Lin and Zhu (2019) propose their own concepts for understanding the concept of green economy. Green growth can be seen as a new source of capital accumulation and job creation (Gibbs, O'Neill, 2017). Factors influencing green growth are analyzed in the works of Guo et al. (2020), Capasso et al. (2019), Du et al. (2019), Adeel-Farooq et al. (2018) and others. Capasso et al. (2019) indicate economic and social barriers to green growth. Song et al. (2019) emphasize that green economic growth is the direction of future economic growth in the world. Kasztelan (2017) states that the concepts of green growth and green economy are linked and that differences between them have become unclear; moreover, they are used almost interchangeably. The aim of green economy and green growth is almost the same, i.e. to identify the ways of improving the results of economic activity taking into account the existing climate problems and increasing deficiency in natural resources (Kasztelan, 2017). However, the concept of green economy is more related to economic transformation in order to improve social welfare and justice and to reduce environmental threats and ecological deficiencies. Meanwhile, green growth is strictly connected with the idea of green economy (UNEP, 2011)

in order to achieve continuing economic growth, at the same time recognizing the role of natural capital and ensuring climatic and environmental sustainability.

Literature search has helped to reveal a few studies which attempt to evaluate green growth (Pan et al., 2019; Kararach et al. 2016). It is agreed that GDP or GDP per capita are not appropriate indicators to analyze green growth of a country. First attempts to propose sets or frameworks of green growth indicators have been made by OECD (2011), UNEP (2012), and other international institutions. Although some research (Pan et al., 2019; Kararach et al. 2018) has been carried out on the evaluation of the green growth index, there is still very little scientific understanding of the possibilities of green growth evaluation. Quantitative analyses of green growth have been conducted by Lyytimäki et al. (2018), Kararach et al. (2018), Yang et al. (2019), but it should be noted that these studies are based on the investigation of various indicators. Furthermore, the application of scientists' designed green growth indices differs. Therefore, the *scientific problem* can be formulated as follows: what methodologies can be used to evaluate the green growth parameters and results of a country.

The *purpose of this article* is to evaluate the European Union countries according to the developed Green Growth Index.

The *object* of the paper is the evaluation of green growth.

Three primary aims of this study are determined as follows:
1. To identify factors influencing or stimulating green growth.
2. To analyze sets, frameworks, and indices of green growth indicators designed by international organizations and scientists.
3. To develop an index and to evaluate green growth in the European Union countries.

Research methods: scientific analysis, systemizing and generalization, analysis of green growth measurement possibilities proposed by international organizations and scientists during the period of 2012-2019, secondary data analysis, estimation of green growth in the European Union countries in 2018 on the basis of the designed index.

This scientific theoretic paper provides with an overview of the discourse on green growth assessment methods, the existing green growth measurement tools, the design of the Green Growth Index and its application for the European Union countries.

2. Discourse of Green Economy and Green Growth

In recent years, interest in green economy and green growth has been growing. There is a need to replace the traditional economic models in order to address various environmental issues and key economic challenges. Moreover, several policy initiatives have been suggested and implemented for transitioning to a green economy (Lindman, Söderholm, 2016). A concept of green economy has been introduced by Pearce et al. (1989) in response to the undervaluation of environmental and social costs in the current price system. Since then, it has been expanded (see Table 1).

Table 1. Alteration of the definition of Green Economy

Variations of the definition of Green Economy	Author(s)	Year
A way to substitute renewable energy and low-carbon technologies for fossil fuels, and to improve resource and energy efficiency.	UNEP	2011
An economic development based on the sustainable development model and knowledge of ecological economics.	Popa et al.	2011
A term for the growth of the entire economy.	Jänicke	2012
A concept is that low-carbon energy technologies have considerable potential to achieve socio-economic objectives alongside environmental ones.	Pahle et al.	2016
An "umbrella" concept that encompasses different implications with regard to growth and well-being, or efficiency and risk reduction in the use of natural resources.	Loiseau et al.	2016
An integrated, economy-wide framework contrasts with many previous sustainable development initiatives that have been more sector or site focused.	Swainson, Mahanty	2018
A broad concept that includes different interpretations, definitions and practices ranging from the greening of current neoliberal economies to radical transformations of these economies.	Bergius et al.	2018
A way for solving environmental problems that shows confidence in human ingenuity and technological advancements.	Gazzola et al.	2019
A resource-saving and environment-friendly economy.	He et al.	2019
A socially inclusive and economically beneficial yet environmentally sustainable alternative.	Laibach et al.	2019
An efficient way for sustainability, which focuses on economic growth, resource conservation, and environmental friendliness.	Lin, Zhu	2019

Source: developed by the authors according to the mentioned scientists

As it can be seen in Table 1, almost all definitions of green economy include economic growth. In order to meet climate and energy targets, participation of disparate agents should be involved (Paroussos, Fragkiadakis, Fragkos, 2019). Green economy is seen as a new source of capital accumulation and job creation (Gibbs, O'Neill, 2017), a way to achieve sustainable development (Lin, Zhu, 2019), direct valuation of natural capital and nature's services (Popa et al., 2011). Moreover, the expansion of green economy is related to energy generation, resource use and environmental management (Popa et al., 2011). Li et al. (2015) indicate a need to encapsulate three sectors (industry, people, and government) in order to create green economy. Meanwhile, Gibbs, O'Neill (2017) indicate that there is a spectrum of interpretations of the green economy, from

market-led, business-as-usual to proposals for more radical changes such as a steady-state economy and degrowth. Governments in countries across the world increasingly adopt the green growth discourse to underline their ambition for the greening of their economies (Capasso et al., 2019). Notwithstanding, Wanner (2015) emphasizes that in the green growth discourse there is no 'one-size-fits-all' prescription for green growth strategies. This can be explained by differences in contexts of policy and institutional frameworks, economic and political circumstances, levels of development, and economic and environmental interdependencies. Furthermore, advanced, emerging, and developing countries face different challenges and opportunities (OECD, 2011). According to Hickel and Kallis (2020), the notion of green growth emerged as a central theme at the Rio+20 Conference on Sustainable Development in 2012. Since then, green growth is seen as a response to climate change and ecological breakdown and one of key elements in achieving sustainable development (Capsasso et al., 2019; Hichel, Kallis, 2020). "Green growth is about fostering growth and development while ensuring that the natural assets continue to provide resources and environmental services on which our well-being relies" (OECD, 2011, p. 18). The World Bank (2012) relates green growth with an efficiency in using natural resources, minimization of pollution and environmental impact, and resilience of natural capital. Meanwhile, UNEP (2011) emphasizes its role in income growth and improvement of human well-being at the same time reducing environmental risks and ecological scarcities. It should be noted that, according to Hickel and Kallis (2020), the concept of green growth is still new and infinite. According to Song et al. (2019), green economic growth must achieve the following goals: economic growth, job creation, and environmental impact reduction. Paroussos et al. (2019) emphasize that green growth requires that GHG emission reduction takes place at such rate that allows clean energy technologies to become market competitive.

Green growth can be stimulated by increased fiscal spending on public goods, government expenditures on education, increased spending on R&D and innovation process (Lin, Zhu, 2019), substantial financial resources (Mohamed et al., 2014), environmental regulations, support for technology policies and consumer-awareness programs (Holroyd, 2014), market building and the effective workings of the market system (Wanner, 2015), development of infrastructure (Li et al., 2015), fossil fuel scarcity (De Cian et al., 2016), increased technological innovation and efficiency accompanied by foreign direct investments (Nasir et al., 2019), adoption of environmentally friendly technologies (Hille et al., 2019), creation of new, environmentally friendly industries (Dornan et al. 2018), local capabilities (including technologies, institutions, skills) or single sector (Capasso et al., 2019), subsidies and tax incentive policies (Chang et al., 2020), creation of a favourable environment for long-term green investment (Guo et al., 2018; Adeel-Farooq et al., 2018; Geisendorf, Klippert, 2017), building a green finance system (Zhang, Wang, 2019), economic openness and R&D scale (Song et al., 2019), growth of a green bond market (Elliott, Zhang, 2019; Ngwenya, Simatele, 2020).

It should be noted that in this context, economic efficiency and environmental benefits are opposite to each other. But they are related when green growth is analyzed. Pan et al. (2019) raise two questions: what influence has green economic system of a country and how to identify the factors influencing green economy? Different regions vary in their level of socio-economic development and environmental challenges (Guo et al., 2020), thus, countries with the same level of green economy can make different policy choice (Pan et al., 2019) in order to ensure green economic growth. Moreover, there is no obvious evidence about the interactions and dynamics relationships among those factors (Pan et al., 2019). Factors influencing green economy are analyzed in the works of Guo et al. (2020), Capasso et al. (2019), Du et al. (2019). Guo et al. (2020) indicate that green investment banks can leverage the power of private investment to support green infrastructure and technological innovation. Furthermore, Du et al. (2019) emphasize that political factors have high relationship with green investment and these investments reflect the government's emphasis on environmental improvement. GDP, GDP per capita, and fixed assets of investments play important roles in the development of green investments (Du et al., 2019). Adeel-Farooq et al. (2018) find out that economic growth has positive impact on the environmental performance. On the other hand, green growth can also encounter barriers. Capasso et al. (2019) indicate the following barriers to green growth: negative externalities associated with investments in a public good like knowledge; uncertainty of investments; market failure. All these obstacles can slow down growth in developing or economically well-developed countries. Özbuğday et al. (2020) highlight an impact of increased resource efficiency of small and medium-sized enterprises for boosting their productivity, competitiveness and growth generation. Song et al. (2019) emphasize that green economic growth is the direction of future economic growth in the world.

3. Analysis of Green Growth measurement tools

Attempts to evaluate green growth can be found in the scientific literature (Pan et al., 2019; Kararach et al. 2016). According to Pan et al. (2019), green growth asserts that continued economic expansion – measured by GDP – is or can be made to be compatible with planet's ecology. Yaduma (2018) criticizes the use of GDP measures in resource investigations because of the two main reasons. Firstly, it treats the depreciation of physical capital as a positive contribution to national income. Secondly, GDP measures of output do not reflect real incomes of resource-intensive economies as green accounting procedures are not

incorporated. Song et al. (2019) emphasize that in order to calculate green GDP, net natural capital consumption is required (including resource consumptions, environmental damage, and environmental protection and restoration initiatives). Therefore, some attempts have been made to adjust GDP. For example, GDP adjusted for social and environmental costs is in the Index of Sustainable and Economic Welfare, the Measure of Economic Welfare, and the Genuine Progress Indicator. Nahman et al. (2016) indicate other indices: the Human Development Index, the Ecological Footprint and the Environmental Performance Index, Ecological Footprint and the System of Environmental–Economic Accounting. But it should be noted, that in all those indices only a few indicators (2-4 units) are evaluated. Hickel and Kallis (2020) note that many governments have adopted the practice of dividing GDP by domestic material consumption, which measures the efficiency of resource use by an economy. It should be noted that DMC is a problematic indicator because it does not include the material impact involved in the production and transport of imported goods, outsourced production has been shifted off balance sheet (Hickel, Kallis, 2020). Meanwhile, Zhu et al. (2020) indicate that energy consumption is one of the basic indicators to measure the level of economic development of a country. First attempt to propose sets or a framework of green economy/growth indicator has been made by OECD (2011) – this institution proposed green growth measurement framework. Other attempts by international institutions to set up sets or frameworks of green growth indicator are shown in Figure 1.

Figure 1. Green growth measurement frameworks or sets proposed by international organizations
Source: developed by the authors

As it can be seen in Figure 1, OECD, UNEP, Global Green Growth Institute, and the Asian Development Bank have proposed a few sets or frameworks of green economy indicator. In these frameworks and sets, different amounts of indicators are included. For example, GGGI (2019) Green Growth Index analyzes 36 indicators of 115 countries in four dimensions: efficient and sustainable resource use, natural capital protection, green economic opportunities, and social inclusion. Meanwhile, the Asian Development Bank (2018) proposes a set of 28 indicators that cover economic growth, social equity, and environmental sustainability. It must be emphasized that the index proposed by the Asian Development Bank (2018) has been applied only for calculation of the integrated green growth index in Asian countries.

In practice, some examples of green growth and/or green economy measurement indicators can be also found: the Global Green Economy Index (GGEI), the Green Economy Benchmark Index (QGREEN), the Low Carbon Competitiveness Index (LCCI), the Climate Change Performance Index (CCPI), the Green Economy Index (GEI). It should be noted that all these indicators are more suitable to evaluate companies or cities according to the issues of green growth. Moreover, their application is based only on one dimension or on a few sectors. Thus, Nahman et al. (2016), Kararach et al. (2018), Pan et al. (2019) and others have conducted models for green growth evaluation.

Lyytimäki et al. (2018) emphasize that the indicators of green growth have high expectations to live up to. There is a need for giving of a comprehensive and reliable view of the key socio-economic trends and serving for easy-to-understand and effective tools. Indicators should be: acceptable, comparable, measurable, relevant, and internationally used (Lyytimäki et al., 2018). In Table 2, scientists' attempts to analyze green growth are proposed.

Table 2. Attempts to analyze green growth

Model name	Methodology	Dimensions	Nb. of key indicators	Application	Authors
Green economy index	Index assessment	Economic Social Environmental	26 indicators	193 countries	Nahman et al. (2016)
Key indicators for green growth	Index assessment	Human well-being Ecosystems Economy	19 indicators	Finland	Lyytimäki et al. (2018)
Environmental Performance Index	Econometric model	Green field investment Energy consumption	4 indicators	9 Asian developing countries	Adeel-Farooq et al. (2018)

		Economic growth Urbanization			
Green growth index (GGI)	Index assessment	The socioeconomic context and characteristics of growth Environmental and resource productivity Monitoring the natural asset base Gender Governance	48 indicators	22 African countries	Kararach et al. (2018)
Global productivity index (GPI)	Econometric model	Global Malmquist-Luenberger productivity index	5 indicators	30 provinces in China	Pan et al. (2019)
Green development level	Index assessment	Environment Economy Society	19 indicators	109 cities in China	Yang et al. (2019)

Source: developed by the authors

As it can be seen in Table 2, there are differences in dimensions covered by green growth indices. The majority of indices related to green growth are based on index assessment and include more indicators (from 19 to 48) than the ones that are based on econometric analysis. Moreover, some indices (for example, Lyytimäki et al., 2018) are designed to evaluate only environmental impact on country's economy. Nahman's et al. (2016) proposed Green Economy Index is based not only on statistical data or indices such as Human Development Index, but also on survey on self-reported overall life satisfaction.

Comparing green growth indices proposed by international organizations with those composed by scientists, it should be noted that indices proposed by organizations are applied more widely than the ones proposed by the scientists. Furthermore, some scientists' proposed indices can be applicable only to developing countries, for example, Kararach et al. (2018). In the index designed by these authors, some specific indicators are integrated, for example, HIV/AIDS prevalence (age 15-49). Yang's et al. (2019) proposed Green development level model is suitable for index assessment in cities, because some indicators are relevant only to cities, for example: green area per capita or percentage of green coverage in built-up areas.

In order to give comprehensive and reliable insights, indices should be composed in an easy-to-understand and effective way; indicators included in index calculation should be widely used, measurable, comparable, and relevant. Only then it would be possible to measure green growth of different countries (developed and developing) all around the world. As all indices, proposed by international institutions and scientists, differ, there new has been developed a new index – Green Growth Index.

4. Green Growth Index in the European Union

This study seeks to obtain data which will help to address the gaps of green growth evaluation. For this purpose, an integrative index to evaluate green growth patterns has been developed. This index is based on the Inclusive Green Growth Index (IGGI) proposed by the Asian Development Bank (2018) and is supplemented with some economic indicators included in indices proposed by Nahman et al. (2016), Kararach et al. (2018), and Yang et al. (2019). The design of the Green Growth Index combines the strengths of the existing indices and frameworks into one composite index with a wider coverage of indicators. Besides, these indicators are related to economic, environmental and social dimensions of growth. This index can be applicable for developed and developing countries throughout the world. The proposed index and its pillars are shown in Figure 2.

The following steps have been taken in designing the Green Growth Index:

- Three pillars of the Green Growth Index (Economy, Society and Environment) and 32 indicators are expressed in different units (per cent, euro, number), thus the indicators have been given to scores ranking from 0 to 1, by using the min-max approach. This method assigns the indicators by dividing the difference between a country's indicator performance and the sample minimum value by the difference between the sample minimum and the sample maximum values of indicators of 27 countries (see Equation 1).

$$New\ variable = \frac{variable - min_x}{max_x - min_x} \qquad (1)$$

- Indicators where a higher value implies a worse outcome or where the impact direction is negative (for example, gross general government debt or air pollution) are expressed by using Equation 2.

$$New\ variable = \frac{max_x - variable}{max_x - min_x} \qquad (2)$$

- The indicators for each pillar are assigned by equal weights, because, in our opinion, all three pillars are equally important. Therefore, the average of the normalized scores is calculated. As indicators vary widely between the European Union countries, values of each pillar are also in wide range.
- Countries are ranked according to each pillar group.
- The scores of each of the three pillars are further assigned equal weights and aggregated to compute the score for the Green Growth Index (see Equation 3).

$$GGI = \frac{1}{3}*(\text{average economy}) + \frac{1}{3}*(\text{average society}) + \frac{1}{3}*(\text{average environment}) \qquad (3)$$

Economy	Society	Environment
• Real GDP per capita • GDP per capita growth rate • Trade openness • Age dependency rate • Gross general government debt • R&D expenditures • Adjusted net savings	• Unemployment rate • Employment rate • Life expectancy gender gap • Pupils enrolled in primary education • Labor force participation gender gap • Life expectancy at birth • Infant mortality rate • Access to improved sanitation • Access to improved water • Gini coefficient on inequality • Poverty gap • Mean years of schooling • Population with secondary education • Students in tertiary education • Number of beds in hospitals and health centers	• Natural resource rent • Renewable freshwater resources • Water productivity • Air pollution • Greenhouse gas emmision • Primary energy consumption • Use of renewable energy • Share of environmental taxes in total tax revenues • Resource productivity and domestic material consumption • Recycling rate of municipal waste

Figure 2. Pillars and Indicators of the designed Green Growth Index
Source: Adopted from the Asian Development Bank (2018), Nahman et al. (2016), Kararach et al. (2018), Yang et al. (2019).

Sample countries and data collection. Secondary data on the thematic area of Green Growth have been collected for all 27 European Union countries. Data have been collected from Eurostat, the World Bank databases and UNDP Human Development Reports for the year 2018. The European Union countries have been selected for the evaluation of the Green Growth Index due to uniform regulation of goals set for the implementation and achievement of green growth, as well as data availability for all the selected countries.

Results. According to the designed Green Growth Index (GGI), all three pillars have been evaluated for the European Union countries in 2018. In Figure 3, the average each country's economy pillar and the average of the EU-27 countries are shown. Luxembourg's indicators included in the economic pillar calculations have been above average or the highest ones. After the calculation of all indicators and estimation of average of country's economic pillar according to included rates, Luxembourg's economic pillar has exceeded 1, i.e. it was 1.41.
Figure 3. Economy pillar of the Green Growth Index, 2018
Source: developed by the authors

As it can be seen in Figure 3, according to data of 2018, 13 countries of the European Union have exceeded the average of the Economy pillar. The European Union countries according to the Economy pillar of the Green Growth Index are distributed between 0.3 and 1.41. The highest score (1.41) is for Luxembourg. This result has been achieved due to high level of GDP per capita and trade openness indicators and low rates of age dependency and governmental debt. Meanwhile, the lowest score (0.3) is in Greece. Government debt rate is the highest and adjusted net savings are the lowest ones in Greece.

The average each country's Society pillar and the average of the EU-27 countries are represented in Figure 4. The indicators included in the calculation of the Society pillar vary widely between the European Union countries and, therefore, average country's Society pillar has not reached 1.

Figure 4. Society pillar of the Green Growth Index, 2018
Source: developed by the authors

As it can be seen in Figure 4, Belgium, Czechia, Denmark, Germany, Estonia, Ireland, France, Cyprus, Netherlands, Austria, Slovenia, Finland, and Sweden exceed the average of the Society pillar. The European Union countries are distributed between 0.3 and 0.8 according to the Society pillar of the Green Growth Index. The highest value (0.8) is in Germany; main factors for this achievement are related to low unemployment rate, high employment rate, high level of pupils enrolled in primary education rate, good healthcare and educational systems. The lowest society pillar value (0.3) is indicated in Romania. The highest rate of infant mortality, the biggest poverty gap and the lowest rate of access to improved water have led to such poor performance of Romania according to the Social pillar of the Green Growth Index.

In Figure 5, the average each country's Environment pillar and the average of the EU-27 countries are shown. The indicators included in the calculation of the Environment pillar vary widely between the European Union countries and, therefore, none of the countries have reached the Environment pillar value of 1. 16 European Union countries are above the average rate which accounts for 0.49. The European Union countries according to the Environment pillar of the Green Growth Index are distributed between 0.29 and 0.64. It should be noted that Belgium, Bulgaria, Czechia, Estonia, Cyprus, Latvia, Luxembourg, Hungary, Poland, Romania, and Slovakia did not reach the average of the environmental rate in 2018. The highest value (0.64) is in Lithuania, and the lowest (0.29) in Poland. The highest level of air pollution, low level of renewable resource use and low recycling rate of municipal waste are the main reasons why Poland is lagging behind the EU-27 average according to the Environmental pillar.
Figure 5. Environment pillar of the Green Growth Index, 2018
Source: developed by the authors

In overall measurement, the results of separate three pillars of each country have been accumulated. In Figure 6, the overall Green Growth Index for the European Union countries shows the main results of Green Growth evaluation of data of 2018.

Figure 6. The Green Growth Index in the European Union countries, 2018
Source: developed by the authors

Among the countries in the sample of 2018, the lowest Green Growth Index is (0.38) in Romania and the highest (0.81) in Luxembourg. In order to provide the most comprehensive analysis of Green Growth Index, countries have been ranked on the basis of each pillar and overall index (see Table 3).

Table 3. Ranking of he European Union countries according to the pillars of Green Growth Index and the overall index

Country	Society pillar	Society pillar	Environment pillar	Overall GGI	Country	Society pillar	Society pillar	Environment pillar	Overall GGI
Belgium	25	10	19	22	**Lithuania**	12	21	1	10
Bulgaria	16	26	24	24	**Luxembourg**	1	15	20	1
Czechia	11	7	23	13	**Hungary**	5	22	21	14
Denmark	9	6	10	7	**Malta**	3	17	6	8
Germany	17	1	9	5	**Netherlands**	4	3	14	3
Estonia	8	11	26	16	**Austria**	10	5	8	6

Latvia	18	20	17	18					

Source: developed by the authors

As it is provided in Table 3, Luxembourg, Ireland, Netherlands, Sweden, and Germany perform the best according to Green Growth Index. Meanwhile, Romania, Greece, Portugal, Bulgaria, and Italy are among the worst according to this index. This is due to the fact that these countries underperform according to all three pillars of Green Growth Index.

To summarize, countries in regard to Green growth pillars – Economy, Society and Environment – differ according to Green Growth Index. Main reasons are: low economic growth and poor rates of environmental sustainability. It should be noted that countries' managing bodies should pay more attention to improve lagging indicators in order to achieve higher results in green growth ranking and evaluation.

Conclusions

The concept of green growth encompasses different notable variables, listed by various scientists and methodologies. The main reasons are: different context of country's policy, different level of country's socio-economic development, the existence of economic and environmental interdependencies.

Green growth can be stimulated by increased fiscal spending on public goods, government expenditures on education, increased spending on R&D and innovation process, environmental regulations, support for technology policies and consumer-awareness programs, fossil fuel scarcity, subsidies and tax incentive policies, building a green-finance system, economic openness and R&D scale, and other measures.

OECD, UNEP, Global Green Growth Institute and the Asian Development Bank have proposed a few frameworks for the evaluation of Green Growth indicator, however they include different indicators. The majority of scientists' proposed indices created to evaluate green growth are based on the principle of index assessment. It should be noted that international organizations' proposed indices are applied more widely than those that are proposed by scientists. In order to give a comprehensive and reliable insight, indices should be composed in an easy-to-understand and effective way; indicators included in index calculation should be widely used, measurable, comparable, and relevant.

The results of the Green Growth Index assessment show that green growth is uneven in the European countries; the Green Growth Index and all three pillars vary between countries due to the fact that several countries (Romania, Greece, Bulgaria, Portugal, and Poland) lag behind all the indicators included in the Green Growth Index. Meanwhile, Luxembourg, Ireland, Sweden, Malta, and Netherlands have achieved the highest level of green growth. The Green Growth Index can be widely applied to evaluate green growth in developing and developed countries and to compare the countries.

Abstract. The relevance of the subject matter is conditioned by the fact that human resources are an invaluable asset of any organisation, institution, or industrial enterprise. The purpose of the paper is to develop recommendations for managing human resources. The leading methods of researching the problems of the paper include the analysis of theoretical sources, the analysis of statistical indicators, and comparison. Analysis of statistical indicators plays a crucial role in the study, since data on human resource management can be directly obtained from statistical databases. The paper investigates the concept of human resources, the essence of human resource management, the functions of the HR service, analyses the management of human resources at Russian enterprises (in the Khanty-Mansi Autonomous Okrug and the Yamalo-Nenets Autonomous Okrug), identifies management problems, and develops solutions to them. An effective system of performance appraisal, remuneration, and wage structure will increase the effectiveness of the approach to managing human resources, and will lead to fundamental changes in the worldview of the company's management in relation to its human resources. The materials of the paper are of practical value for improving the management of human resources at Russian enterprises.

Keywords: training; potential; enterprise; globalisation; modern economy

1. Introduction

Human resources play a decisive role in the development of a modern economy. Human resource management (HR management) is a collective term for all formal systems created to help manage employees and other stakeholders within an enterprise. Starting with finding the right workforce and ending with retaining the best workforce, the HR service strives to make smart recruitment decisions through human capital analysis (Meena, & Parimalarani, 2019). The role of human resources management is to find the best way to increase enterprise productivity at the expense of its employees. The rational use of human resources of the enterprise allows more efficient use of equipment, machines, mechanisms, and as a result, production volumes, profit, and other economic indicators increase (Melnyk et al., 2019; Fedotov et al., 2018).

Despite the ever-increasing pace of change in the corporate world, the role of human resource management is unlikely to undergo dramatic changes. In recent years, several business tendencies have had a significant impact on human resources management. 21st century human resources management is becoming more efficient with the best use of technological advances (Reddy, & Lakshmikeerthi, 2017; Yessilov, & Kalashnikova, 2015). The main one is new technologies, especially in electronic communications, dissemination and information retrieval, which have radically changed the business landscape. Satellite communications, computers and network systems, fax machines and other devices – all this contributed to a change in the way enterprises interact with each other and their employees (Kerimov et al., 2018a; Kerimov et al., 2018b). For example, teleworking has become a very popular option for many employees, and human resource managers have had to develop new guidelines for this emerging subgroup of employees. Changes in the organisational structure have also affected the change in the nature of human resource management. In recent years, the number of trade unions in many industries has been declining, and organisational philosophy is changing. Many companies have abandoned or adjusted their conventional hierarchical organisational structures in favour of more flat management structures (Silagadze et al., 2019; Miethlich & Šlahor, 2018).

The third factor of change was the acceleration of the globalisation of the market. This phenomenon has led to increased competition for both customers and jobs. Enterprises began to demand higher results from their employees. Other factors that have changed the nature of human resource management in recent years include new managerial and operational theories, rapidly changing demographics, and changes in government employment laws (Yessilov, 2015; Lapidus et al., 2018a; Lapidus et al., 2018b). The role of the human resources management service is constantly increasing. Currently, businesses need people with a new mindset to cope with a changing global environment. There is a need for reengineering HR processes. Career planning needs to be clearly defined for employees. Management should also encourage employee participation in decision making. The theoretical significance of the paper lies in the study of the essential and substantial features of human resource management in the enterprise. The practical significance of the paper lies in proposing areas for improving the management of human resources in the enterprise. The theoretical framework of the paper comprises fundamental developments on the subject matter, which were presented in the works of domestic and foreign authors (Tretyakova et al., 2020).

Many authors paid addressed the issues of human resource management in the enterprise and suggested ways to solve them. S. Zeidan and N. Itani (2020) consider that human resources analysis is important for working with human resources, upon implementing which enterprises face a lack of skills in analysing personnel data, poor IT infrastructure and insufficient business investments. The interconnection and interaction of effective human resources management and strategic planning allow organisations to achieve maximum success (Stewart, & Brown, 2019). From the standpoint of D. Angrave and I. Kirkpatrick (2016), human resources management should consider both staff potential and shortcomings, HR service personnel should be involved in building an operational and strategic plan to develop better methods and approaches – in this case, the practice of working

with personnel will lead to transformational changes. However, the literature does not contain any relevant studies of the problems of human resource management in specific enterprises, which will be further discussed herein.

2. Literature Review

Resources form a part and a fundamental framework of the enterprise, since the enterprise cannot function without resource supply. The most important results of effective resource potential management are minimising the costs of their storage and management, timely provision of the necessary amount of resources for uninterrupted production and maximising the level of satisfaction of the needs of consumers of enterprise products.

The enterprise possesses various resources:

− material resources (items and means necessary for the smooth functioning of the production process);
− intangible resources (allow to develop and patent individual approaches to production management);
− technology (provides the conversion of material resources into goods);
− financial resources (provide the mobilisation of funds to start the production process);
− information resources (allow to exchange information between departments and with the external environment, allow to automate the management of various processes);
− innovative resources (allow to get product, technological and organisational advantages over competitors);
− human resources (personnel of the enterprise, which performs all basic functions);

Human resources, therefore, constitute an important component of enterprise resources, including staff and workforce capacity. According to Z.Yu. Pronina (2018), human resource management is the employment, development, promotion of people in organisations and the development of appropriate relations between management and employees. HR management is the activity on the optimal use of personnel to achieve the goals of the enterprise, on the formation of personnel policy, corporate culture, management of human resources behaviour, management of social and labour relations (Lapshova, 2020).

HR management is based on the following basic principles. Firstly, human resources are the most important assets of an enterprise, and their effective management is the key to success. Secondly, personnel policy and personnel processes should be associated with the achievement of corporate goals and strategic plans. Thirdly, the corporate culture and values, the organisational climate and managerial behaviour arising from the corporate culture influence the results of the entire enterprise. Fourthly, HR management is involved in integration – involving all members of the enterprise in organisational practice and working together with the understanding of common tasks to achieve the goals of the enterprise (Konyavsky & Ross, 2020; Bashynska, 2015).

The HR service develops programmes and activities aimed at helping meet both individual and organisational needs, goals, and objectives. With the help of human resources, it forms the appropriate corporate culture and implements programs that support the core values of the enterprise. Personnel workers study and analyse the environment, plan human resource requirements, recruit personnel in accordance with the needs of the enterprise, evaluate the labour behaviour of workers, establish compensation, improve working conditions, maintain effective labour relations (Dudin et al., 2016). Personnel workers aim at a qualitative improvement of the human resources of the enterprise, which are considered to be the most valuable assets (Miethlich & Oldenburg, 2019).

The responsibilities of HR management can be divided into three categories: individual, organisational, and career responsibilities. Individual management involves assisting staff in identifying their strengths and weaknesses, correcting deficiencies and making the best contribution to the development of the enterprise. These

responsibilities are carried out through various activities, such as validation, training and testing. Organisational development focuses on creating a successful system that maximises human (and other) resources as part of larger business strategies. This important responsibility also includes creating and managing a change program that allows the organisation to respond to changing external and internal influences. Finally, there is responsibility for managing career development. This entails the selection of people most suitable for certain jobs and the development of a career path within the enterprise (Frolova et al., 2020; Zatsepin et al., 2018).

The structures of HR services vary widely depending on the business, and are formed depending on the type, size, and guidelines of the enterprise. In recent years, staffing has changed due to internal organisational changes, as well as against the background of external changes (demography, globalisation, information technology) (Ben-Gal, 2019). Currently the HR service is considered not as an administrative unit of the enterprise, but as a strategic business partner. The determining factor in supporting the long-term functioning of the enterprise and its development in a changing economic environment is the use of a strategic approach. Building an effective personnel strategy in close integration with the overall corporate strategy of the enterprise constitutes the framework for creating a competitive advantage based on the main element of any enterprise – its human resources. Accordingly, the leadership of modern organisations is facing a vexed question of choosing an effective personnel strategy that would meet the challenges of a changing external environment, but at the same time maintain and strengthen the competitive advantages inherent in organisations (Mukhamadiyeva et al., 2018).

Each company has its own preferences in the use of personnel management tools. Authors such as G.J. Bamber et al. (2017) believe that the creativity and innovation of human resources help challenge old ways of thinking and find new solutions to current problems. According to D. Ulrich (2016), lately, special attention has been paid to such features of human resources as determination, engagement, and welfare. An effective motivation system is important to attract and retain staff. An interested employee is a productive employee, which means a more profitable employee. The physical presence of a person does not guarantee their effective work. Only being at the workplace at their own free will and desire, the employee will make maximum effort, and not seek interest in other activities. It is motivation that drives human reserves. Labour motivation forms an integral part of the human resources management system, which constitutes a set of incentives that determine the main parameters of labour activity (Gorelov et al., 2016; Akizhanova et al., 2018).

Motivation can be material and non-material. Recently, the methods of motivation that produce results are as follows: bonus depending on the results of the work, holding contests, rewarding staff, financial support, conducting surveys, providing more freedom and flexibility in work, creating comfortable working and relaxing conditions, healthcare. For example, the founder of Radioactive Public Relations decided to try a four-day work week without reducing staff salaries. Six months later, the results spoke for themselves – the agency continued to conquer a new business, staff retention remained at 100%, and the number of sick days was reduced by 75%. Business revenue has more than doubled every year (Goodall, 2019). Mountain View organisation (California) pays special attention to the workplace environment – the campus area resembles old subway cars, there are conference rooms decorated in Broadway style. Google allows its software developers to design their own desktops or desktops made of what looks like huge Tinker toys. While some engineers have fixed tables, some others have additional treadmills that allow them to walk while working (Luenendonk, 2014).

3. Materials and Methods

The main method used in the analysis of human resource management is the analysis of statistical indicators. Large companies publish information on personnel and social policies and personnel statistics on their websites; the author selects the following indicators: staffing levels; staff turnover; number of employees taking part in training events; skill level of employees; staffing level. With that, to calculate individual indicators, it is necessary to study data for several years (those indicators were considered, that were available in the annual reports of

individual companies under study). As the empirical framework of the study, we selected indicators for human resource management of companies located in the Yamalo-Nenets Autonomous Okrug and the Khanty-Mansi Autonomous Okrug.

It is important to describe the enterprises of the Yamalo-Nenets Autonomous Okrug and the Khanty-Mansi Autonomous Okrug. Khanty-Mansi Autonomous Okrug is a large oil and gas region of the Russian Federation and one of the largest oil-producing regions in the world. Yamalo-Nenets Autonomous District ranks 1st in Russia in terms of production of natural gas and gas condensate, oil is also produced here. The vast majority of successful companies in the Khanty-Mansi Autonomous Okrug and the Yamalo-Nenets Autonomous Okrug represent the oil and gas industry, gas and oil transport, and equipment for this industry.

The study of the problem was carried out in three stages:

– at the first stage, a theoretical analysis of the existing methodological approaches to the analysis of human resource management was carried out, statistical indicators were selected for analysis;
– at the second stage, the selected indicators were studied in dynamics, indicators for different enterprises were compared;
– at the third stage, general conclusions were drawn regarding human resource management at enterprises of the Tyumen region, proposals were developed to change the situation for the better.

4. Results

We shall consider the features of human resource management on the example of individual enterprises of the Tyumen region: UTEC-Koda JSC, Rosseti PJSC, Tyumen Rosseti JSC (formerly Tyumenenergo JSC until 2019), Surgutneftegaz PJSC. In UTEK-Koda JSC (Khanty-Mansi Autonomous Okrug) personnel work includes the processes of selection, fitting, hiring, placement, motivation, and staff training. The average headcount is 130 people (according to data for 2019). If we consider the management of personnel motivation at UTEC-Koda JSC, then the following methods of stimulating employees were developed there:

− employees receive cash compensation in honour of a professional holiday (Power Engineers' Day) in an amount that depends on the financial situation at the enterprise;
− at the birth of a child, financial aid is provided in the amount of 10 thousand roubles;
− on birthday – 50 years, and then every 5 years a paid day off is provided and 10 thousand roubles are given out as material aid;
− upon reaching 30, 35, 40, 45 years, 5 thousand roubles are given;
− one of the family members of the deceased employee of the enterprise (due to disease, accident not at work) is aided 15 thousand roubles;
− reimbursement of the burial expenses in case of death of an employee as a result of a production-related accident, as well as the death of a disabled person resulting from a work injury at the enterprise or occupational disease, at the lowest rates, but not exceeding 25 thousand roubles;
− in case of death of close relatives, financial aid is allocated to employees of the enterprise in the amount of 10 thousand roubles;
− in cases of natural disasters, emergencies, fires, floods, etc., financial aid is allocated to employees – 25 thousand roubles;
− the costs of preschool education are compensated to parents (employees of the enterprise);
− transport expenses (excluding taxis) are paid to employees for travel to the place of vacation within the territory of the Russian Federation and back;
− in case of retirement, lump-sum benefits are paid: for work experience of up to 10 years – twice the size of the allowance, calculated from the average monthly income, from 10 to 15 years – three times, from 15 to 20

years – four times, over 20 years – five times;
−   parents with children under 17 years old are given New Year gifts.

For the purpose of additional motivation, an honour board has been posted on the company's website, and additional medical insurance is provided. One of the important indicators of the integrity and stability of an organisation is staff turnover. A low staff turnover rate indicates a high level of social security of employees and an effective approach to personnel management. We shall consider the dynamics of staff turnover in JSC "UTEC-Koda" in Figure 1.

■ staff turnover, %

Fig. 1. The dynamics of staff turnover in UTEC-Koda JSC in 2015-2017, %

Source: compiled by the author based on data from (Media Information, 2020).

According to available data obtained from the annual reports of UTEC-Koda JSC for 2015-2017 we can conclude that the level of turnover in this company is high and increased annually in the analysed period. That is, the measures taken regarding human resources management in this company are not enough to retain employees. We shall compare staff turnover at UTEK-Koda JSC with the same indicator at Rosseti PJSC (Fig. 2).
■ staff turnover, %

Fig. 2. The dynamics of staff turnover in JSC "Rosseti" in 2015-2018,%

Source: compiled by the author based on data from (Company's News, 2020).

This company is much larger than UTEC-Koda JSC. The average number of employees of PJSC Rosseti in 2018 amounted to 217 thousand people (including the number of JSC ROSSETI Tyumen over 7 thousand people). The staff turnover in this company in 2015 was 4.9%, and in 2016-2018 was at the level of 4.5%. This level of turnover is in line with the standard and its decrease is a positive fact. The functions of the HR service of PJSC Rosseti include: workforce planning, selection, performance appraisal, salary administration, training,

development, provisioning, assessment, dismissal. To professionally evaluate the competence and potential of the chief engineers of the subsidiaries and affiliates of PJSC Rosseti, comprehensive assessment activities are regularly carried out with regard to the heads of technical units to the level of electric grid areas (for example, in 2018, over 2 thousand people were evaluated). At all levels of management, a personnel reserve is created. In 2018, the number of updated personnel reserves of subsidiaries and affiliates for senior positions totaled about 15 thousand people. About 70% of appointments to managerial positions are secured by internal candidates. We shall consider the dynamics of the share of employees with professional education and the level of staffing in 2015-2017 in JSC "Rosseti Tyumen" in Figure 3.

Fig. 3. Dynamics of the share of employees with professional education and staffing levels in 2015-2017, %
Source: compiled by the author based on data from (Energy News, 2020).

The employees of Rosseti Tyumen JSC noted a high level of staff qualification – in 2017, 85.7% of employees had professional education. This indicator has increased by 4.7 percentage points since 2015. The staffing level of JSC Rosseti Tyumen during 2015-2017 was maintained at a fairly high level of not less than 97%, compared to 2015, the growth was 4 percentage points. The methods of incentives in the company include: establishing a high level of wages, establishing the dependence of wages on the level of productivity and on achieving performance targets, the dependence of wages on the conditions of production activities, promotion of state, industry and corporate awards, assistance in improving housing conditions, additional insurance, organisation of cultural and sports events for employees and their families, etc.

The company has adopted the Digital Transformation 2030 Concept, in accordance with which digital projects have already been implemented in the area of interaction with personnel: conducting evaluation activities with the use of remote testing forms, launching a project to unify and automate HR management business processes aimed at implementing the platform providing a digital format for all personnel processes, which will allow for monitoring and development of the company's work throughout the country. The system of training, retraining, and advanced training is important at all enterprises of the oil and gas industry (Guliyev et al., 2017).

For example, in 2017, employees of UTEK-Koda JSC attended the following advanced training courses: "Civil defence and protection against natural and anthopogenic emergencies", "Labour protection for managers and specialists", "Fire Safety Basics for managers (FSB) and those responsible for fire safety", "Electrical safety", "Electrician for testing and measuring of 4th category". For the following programmes: "Activities in "Preparation and presentation of financial statements of a business entity", "Software Engineer", "Technosphere Security", attended the following seminars: corporate seminar-workshop "On recognition of accounting regulations by federal standards (FSBU). Other relevant changes in the regulatory and legislative framework in

accounting", "Installation of VLI-0.4 kV, VLZ-6/10 kV with ABC cables. Installation of cable joints 1-35 kV. Innovations in the electric power industry"; workers took part in the electrical engineering forum.

In 2018, Rosseti PJSC received 132 thousand employees or 61% of the total number of employees trained in 2018, in 2016 this indicator was 50%, and in 2017 – 58.7%. That is, there is an annual increase in the number of trained personnel. If we consider the educational activities implemented with the use of training simulators and remote forms of self-training, then the total coverage of employees with training programmes constitutes 100%. We shall analyse the training of personnel at JSC Rosseti Tyumen in 2017-2018 (Table 1).

Table 1. Analysis of personnel training at JSC Rosseti Tyumen in 2017-2018

Indicator	2017	2018	Absolute change
Number of employees taking part in training events, people	3,597	3,659	62
The total number of staff	7,418	7,375	-43
The share of employees taking part in training events in the total number of staff, %	48.5	49.6	1.1

Source: compiled by the author based on data from (Energy News, 2020).

The number of employees taking part in training events at JSC Rosseti Tyumen in 2017-2018 increased by 62 people, the share of employees taking part in training events in the total number of personnel increased by 1.1 percentage points, although in comparison with PJSC ROSSETI it is much lower. Next, we shall analyse the training of personnel at Surgutneftegaz PJSC in 2017-2018 (Table 2).

Table 2. Analysis of staff training at Surgutneftegaz PJSC in 2017-2018

Indicator	2017	2018	Absolute change
Number of employees taking part in training events, people	31	33.3	2.3
The total number of staff	113.6	112.8	-0.8
The share of employees taking part in training events in the total number of staff, %	27.3	29.5	2.2

Source: compiled by the author based on data from (PJSC "Surgutneftegas", 2020).

The number of employees taking part in training events at Surgutneftegaz PJSC in 2017-2018 increased by 2.3 thousand people, the share of employees taking part in training events in the total number of personnel increased by 2.2 percentage points, although in comparison with PJSC Rosseti and JSC Rosseti Tyumen it is much lower – only a third of employees annually improve their level of professional knowledge (Kerimov et al., 2019).

As for the personnel policy in Surgutneftegaz PJSC, the company has a comprehensive system of employee motivation, developed with consideration of strategic objectives of the Company. Motivation tools here include: annual indexation of wages, encouragement (once a year and once a quarter) for the performance of production and technical and economic indicators, bonuses for the performance of especially important tasks, rationalisation work, import substitution, and development of new technologies. Surgutneftegaz PJSC organises "Best in Profession" professional contests and drill crew competitions. This contributes to an increase in the efficiency of employees, helps to creatively address current production matters.

Discussion

Having analysed the management of human resources at the enterprises of the Tyumen region, we can draw certain conclusions:

1. In UTEC-Koda JSC, personnel work includes the processes of selection, fitting, hiring, placement, motivation, and staff training. The company has developed a considerable number of ways of motivation: staff at the enterprise are motivated by provision of financial aid in difficult life situations, allocation of rewards on individual holidays, parents are compensated for the costs of preschool education and New Year gifts are presented, corporate trips, leisure trips are organised, photos of advanced workers are placed on the board of honour, the possibility of additional medical insurance is in place. The company has developed a continuing education program. However, despite the measures taken in relation to human resource management, for 2015-2017, the turnover rate in this company was high and increased annually during the analysed period.

2. The functions of the HR service of PJSC Rosseti include: workforce planning, selection, performance appraisal, salary administration, training, development, provisioning, evaluation, dismissal. The company has adopted the Concept "Digital Transformation 2030", in accordance with which digital projects have already been implemented in interaction with personnel. In this company, low staff turnover is noted over several years, which proves the effectiveness of the ongoing personnel policy.

3. Rosseti Tyumen JSC is part of Rosseti PJSC. The employees of this company have a high level of qualification and a high level of staffing. The company established high salaries, which depend on the level of productivity, on the achievement of performance targets, on conditions of production; employees are encouraged by state, industry, and corporate awards.

4. PJSC Surgutneftegaz has a comprehensive employee motivation system developed with consideration of strategic objectives of the company. Motivation tools here include: annual indexation of wages, bonuses for performing production and technical and economic indicators, bonuses for performing especially important tasks, work on improvement by modification, import substitution, mastering of new technologies, professional skills contests are held. A third of employees annually increase their level of professional knowledge.

The analysis results suggest that in individual companies, mainly in larger ones, the level of staff turnover is lower, which can be explained by a more thought-out policy regarding personnel. In those companies where most of the staff is covered by training programs and digital projects are used in personnel policy, the staff works more stably, contributing to the development of the company. As for the development of improving human resource management, various authors express different opinions. According to N.P. Romanova (2019), it is necessary to study systematically the claims of employees with a view to the rational use of human potential, as there is a correlation between job satisfaction and labour productivity. E. Zavyalova et al. (2017) believe that it is necessary to involve personnel in strategic goal-setting and corporate decision-making, to develop channels of internal and external communication, to provide regular feedback on the performance of employees of all levels, to apply modern methods of personnel assessment, to stimulate various forms of long-term employment (for example, guarantees of a share of profit from the activity of an enterprise).

The authors think that in order to improve the management of human resources at enterprises, the following is necessary: to use digital technologies at all stages of working with personnel, which will improve the efficiency of personnel processes (automate personnel selection, training, assessment, analysis of the reasons for dismissal); it is necessary to study the information on the potential of employees in full detail and use it to achieve the goals of the enterprise; to form a personnel reserve for all employees, and not just for managers; widely introduce intangible instruments of motivation (awards, acknowledgements, flexible work schedule, etc.), accept students for internships, hold open days to form a positive image of the enterprise. Thus, enterprises have the resources and opportunities to improve human resource management. This requires the use of modern tools in the personnel field. Currently, part of the enterprises more successfully manages personnel, another part – less so. Basically, the larger the enterprise, the better its HR management is developed – more motivation tools are applied, the majority

of personnel processes are computerised – as a result, personnel at such enterprises are more stable (low staff turnover).

Conclusions

Summarising the results, we can draw certain conclusions. The organisation's human resources constitute one of its largest investments. Human resources constitute the totality of all components (skills, creative abilities) that employees of an enterprise possess. It is the personnel who are responsible for the growth and prosperity of the enterprise, therefore, they need to be treated with attention to maximise their potential in the interests of the enterprise. The efficient use of human resources in an organisation depends on the effective management of human resources. The main responsibilities related to human resource management include: analysis of work and staffing, organisation and use of the workforce, measuring and evaluating the effectiveness of the workforce, introducing employee remuneration systems, professional development of employees, and maintaining the workforce.

The main issues identified in the course of the analysis of indicators describing human resource management at individual enterprises of the Tyumen region (in the Khanty-Mansi Autonomous Okrug and the Yamalo-Nenets Autonomous Okrug) are as follows: high turnover of staff and its growth were noted at UTEC-Koda JSC; at Surgutneftegaz PJSC, only the third part of the employees annually increase their level of professional knowledge (in PJSC Rosseti – 61%, in JSC Rosseti Tyumen – 49.6%); not all enterprises link HR policies with the Strategy of the enterprise, not all use digital technologies in HR work. Considering the identified issues, recommendations were developed to improve the situation in personnel management. The author's position on improving human resource management is as follows. It is necessary to use digital technologies to a greater extent in personnel work; maximise the study of information on the potential of employees; form a personnel reserve for all employees; widely introduce intangible motivation tools, work with students and schoolchildren (open days, internships).

Adding together all of the above, it should be noted that further studies are required to improve the efficiency of human resource management in enterprises. Currently, individual scientists are studying the nature and features of human resource management, however, the specifics of personnel management and its potential at particular Russian enterprises remain understudied. The most promising direction for further research on the subject matter is to study the experience of leading companies in developed countries, which will help to decide what mechanisms should be applied at Russian enterprises to improve human resource management.

EVALUATION OF THE EFFECTIVENESS OF INSOLVENCY FRAMEWORKS: DOES THE SMALL BUSINESS PERSPECTIVE MATTER?

Salvija Mulevičienė

Mykolas Romeris Law School, Mykolas Romeris University, Ateities st. 20, 08303 Vilnius, Lithuania

E-mail: salvija@mruni.eu

Abstract. The exit of business from the market based on the rules of sound insolvency law is a necessary condition for economic growth. Effective insolvency frameworks encourage entrepreneurship. Currently insolvency laws in many countries are designed with the complexity of medium sized or even large companies in mind, but businesses are very heterogeneous in their characteristics and performance. This paper highlights the importance of taking into account the perspective of individual entrepreneurs, micro, and small enterprises (IMSE) when designing insolvency frameworks. It summarizes the theoretical and empirical literature on the objectives of insolvency law, discusses the unique challenges encountered by IMSEs when facing insolvency, and analyses international standards with the aim of discerning whether the existent instruments offer adequate guidance for policy reforms when designing effective insolvency frameworks and taking into account the needs of small businesses. The aim of this paper is to analyse the specific challenges of insolvent small business: individual entrepreneurs, micro, and small enterprises, and to consider whether existing international standards provide policy makers with sound guidelines and directions for the development of modern national insolvency frameworks that adequately address the needs of small businesses.

1. Introduction

Entrepreneurship and self-employment are recognised as the key enablers of smart, sustainable, and inclusive growth (United Nations, 2017; European Commission, 2012). Growth and productivity need to be supported by competitive and efficient markets, and structural reforms that remove bottlenecks in the business environment (European Commission, 2019). A conducive business environment, including institutional and regulatory settings, is essential to incentivise risk-taking and experimentation by entrepreneurs, and foster business growth potential (OECD, 2018). Evidence suggests that the exit of firms from the market based on the sound insolvency law rules is a necessary condition for economic growth, and effective insolvency frameworks may in fact encourage greater entrepreneurial activity and new firm creation (Cirmizi, Klapper, & Uttamchandani, 2010; McGowan & Andrews, 2016). At the level of European Union (EU) policy, effective insolvency frameworks are also singled out as one of the most important determinants of a Member State's business environment in that regard (European Commission, 2019). At the scientific level, it has long been recognised that when innovative activity in an industry increases, firms' overall survival rates often decrease, but those that do survive tend to be stronger (Nickell, 1996; Klapper, Laeven, & Rajan, 2006; Cirmizi et al., 2010). As highlighted in the recent report of the Organisation for Economic Co-operation and Development (OECD) which introduces the new indicators on the measurement of the effectiveness of insolvency regimes, in the long-run productivity growth is sustained, inter alia, by firms' experimentation with new ideas and the **reallocation** of scarce resources to their most productive uses. So reviving productivity growth will, in part, depend on policies that effectively facilitate the exit or restructuring of weak business (OECD, 2018a) – in other words, on effective insolvency frameworks.

Furthermore, insolvency frameworks have an important secondary effect on entrepreneurship, as many entrepreneurs do not start a company because of their fear of the consequences of business failure. According to the results of the Flash Eurobarometer Survey No. 354 "Entrepreneurship in the EU and Beyond"—which covered the 27 countries currently comprising the EU as well as 13 countries from outside the EU—the fear of bankruptcy and the fear of losing their own home are indicated as the main fears held by the majority of the respondents in starting their own business in Europe (EU Directorate-General for Communication, 2015).

Additionally, insolvency frameworks are of increasing importance not merely in their own right but also because insolvency impinges on a host of other sectors such as the fields of employment, tort, environmental, pension, and banking law. It is essential, therefore, that the development of insolvency law proceeds with a sense of purpose. If lacking a sense of direction, this area of law is liable to be marked by inconsistencies of reasoning and failures of policy (Finch, 1997).

Currently, despite wide-ranging insolvency reforms in many countries, the complexity of regulation, high compliance costs, and ineffective insolvency regimes remain major obstacles to entrepreneurial activity. Upon first glance at this huge array of comparative information, it is clear that the design of each insolvency regime varies significantly across countries (McGowan & Andrews, 2018). However, one general feature can be distinguished: in many countries insolvency laws are designed with the complexity and sophistication of medium sized or even large companies in mind (The World Bank, 2017; Mokal et al., 2018), but the businesses are very heterogeneous in their characteristics and performance. Under the same label of *business* fall individual entrepreneurs, micro enterprises, and small enterprises (together – IMSE), which are vastly different from medium sized companies and the large international firms in relation to employees, access to finances, professional management services, and liability.

Despite the diversity and complexity of the characteristics of small business, until now there has been only little academic research on the effect of insolvency frameworks on IMSEs. But there is a growing awareness that the treatment of small business in insolvency is one of major bottlenecks of the insolvency frameworks (Mokal et al., 2018; Madaus, 2017; Bergthaler, Kang, Liu, & Monaghan, 2015). At the EU level, the EU Entrepreneurship 2020

Action Plan also states that the support measures for small business remain unbalanced, with a substantial number of EU Member States still neglecting to take into account the characteristics of small businesses, in particular micro-businesses, when designing legislation, or not facilitating a second chance for honest bankrupt entrepreneurs (European Commission, 2012). Therefore, national policy makers are advised to assess national insolvency laws applicable to small businesses in the light of good practices (e.g., European Commission, 2000), and when initiating reforms to look for guidance and direction from international expert organisations and best practices examples from other countries.

Only recently are some efforts being seen at the international, regional, and national levels to discuss in more detail the need to find solutions tailored to the specific needs of financially distressed IMSEs, aiming at allowing deserving IMSEs to restart entrepreneurial activities in the light of the broad impact of IMSEs insolvency on job preservation, the supply chain, entrepreneurship, and the economic and social welfare of society (e.g., UNCITRAL, 2020; OECD, 2018a). These discussions started to evolve from the initial question of whether the standards for effective business insolvency, as developed by influential international organisations, are appropriate when applied to a wider group of small and medium sized enterprises, and specifically to the question of whether they are suitable for IMSEs at all taking into account their specific nature. In a recent report, researchers from the United Nations Commission on International Trade Law (UNCITRAL) stated that standard business insolvency processes, where they are costly, complex, lengthy, and procedurally rigid, may be unavailable, prohibitive, or unsuitable for IMSEs. Burdened by unresolved financial difficulties and old debt, IMSEs may be discouraged from taking new risks, may become trapped in a cycle of debt, or may be driven to the informal sector of the economy (UNCITRAL, 2020).

Therefore, the aim of this paper is to analyse the specific challenges of insolvent small business: individual entrepreneurs, micro, and small enterprises, and to find out whether existing international standards provide the policy makers with sound guidelines and direction for the development of modern national insolvency frameworks that adequately address the needs of small businesses.

In order to achieve this aim the following objectives are set:
1) to determine the specific features relevant from the perspective of insolvency law that distinguish IMSEs from other forms of business, and therefore need to be addressed when designing effective insolvency frameworks;
2) to analyse the sufficiency of instruments and good practice guides that address the needs of small businesses and are aimed at supporting governments in designing and implementing effective insolvency policies in that regard.

This paper is an effort to contribute to the emerging scientific discussion on the research question of whether an effective insolvency framework should, and if so – how, specifically address the needs of IMSEs in financial distress and enhance their contribution to inclusive growth. The research is based on a reflective stance by relying on secondary literature, using the methods of comparative and systematic data analysis. The sources of data are the doctrine, legal acts, reports, and working documents of various international and regional organisations such as the World Bank, UNCITRAL, OECD, International Monetary Fund (IMF), EU, and others, related to the effectiveness of the insolvency law, the methodology of its evaluation, the heterogeneity of business, and the perspectives of small businesses.

The paper is structured as follows: first, we will discuss the objectives of insolvency laws. Then, we will analyse the specific characteristics of small businesses and check if they provide for a specific treatment when designing effective insolvency frameworks. The final chapter provides insights on the most influential international standards, focusing on an evaluation of the effectiveness of insolvency frameworks (World Bank, UNCITRAL, OECD, IMF, EU), their key design features, relevant indicators, their suitability to respond to the needs of IMSEs, conclusions, and suggestions.

2. The unique challenges faced by IMSEs in situations of financial distress in comparison to medium sized or large firms

Analyses of contemporary theories on the objectives of insolvency law (Finch, 1997; Azmi & Razak, 2013) show that the interests and needs of the debtor should be taken into account. Therefore, one of the key policy choices to be made when designing an insolvency framework relates to how to balance the objectives to provide the debtor protection and creditor recovery against each other (International Monetary Fund [IMF], 1999).

Currently, the literature and policy papers evidence a consensus that to be effective, insolvency frameworks should be accessible to distressed firms and facilitate exit in a predictable and expedient manner. More specifically, they should: i) incentivize the restructuring of viable firms and the liquidation of non-viable ones at low cost in order to maximise the total value of proceeds to be distributed between creditors, shareholders, employees, and other stakeholders; ii) balance the interests of the parties involved to ensure an equitable resolution without discouraging future risk-taking by investors and entrepreneurs; and iii) provide for a timely resolution of insolvency (McGowan & Andrews, 2016).

While the objectives of insolvency regimes are well-established, there is less consensus on their optimal design (OECD, 2018a). Modern insolvency systems typically have been designed with debtors as larger enterprises in mind (Mokal et al., 2018; The World Bank, 2017). In this chapter, we will analyse if the frameworks and standards that have been developed in, and for, medium-sized or large firms are suitable to be applied to small businesses as well. We will consider whether we might add to this list of objectives an additional one: an effective insolvency framework should respond to the specific needs of financially distressed small businesses.

The first difficulty encountered when conducting research related to small businesses is the apparent lack of a consistent or universally accepted definition of the term *small business*. The definitions and concepts used for identifying small businesses vary significantly among countries at the regional (e.g., EU level) and international level. It is observed that, in most countries, it is an accepted practice to make use of quantitative criteria when defining a small business enterprise (Mokal et al., 2018; Okyere, 2017). The examples of quantitative criteria in defining a small business are: the number of employees; the sales volume; the value of assets; and the market share (Ardic, Mylenko, & Saltane, 2011). For example, in the EU a small business is defined as a business with less than 50 employees but also an annual turnover of below €10 million (EU, 2003).

Despite the variations in applying different measurements, there is a common consensus that the category of small business encompasses the following sub-categories: individual entrepreneurs, micro, and small enterprises (IMSEs).

For the purposes of this paper, we will not rely strictly on the quantitative but rather on the qualitative criteria when defining IMSEs – in other words we will check which shared specific characteristics distinguish them from medium sized and large firms and cause unique challenges in situations of financial distress.

The three main unique characteristics of IMSEs most closely linked with the specific challenges they encounter in insolvency can be distinguished as follows:

1) The first specific characteristic of IMSEs is the blurred distinction between the assets and liabilities of the business and those of the owner.

In contrast to medium-sized or larger firms, in the majority of cases IMSEs are unincorporated, meaning that the debts of the business are personal liabilities of the owner. Even in cases were IMSEs may have a limited liability form, the personal and business debts of micro and small enterprises are often intertwined. This is because lenders that make loans to small enterprises often require the owner to personally guarantee the debt and/or allow the lender to take a lien on the owner's house (Ortiz-Molina & Penas, 2007; Berkowitz & White, 2004; Djankov, Hart, McLiesh, & Shleifer, 2008). These guarantees and liens abolish the legal distinction between the corporation and its owner for the purposes of the particular loan, and as it is rightly pointed out act as an equivalent to "contracting out" the limited liability protection (Cumming, 2012).

As recognized in the literature and EU reports (Bergthaler et al., 2015; European Commission, 2013), the complex, lengthy, and rigid procedures, required expertise, and high costs of insolvency often fail to adequately meet the needs of micro and small business which are also owned and operated by families who have pledged their personal assets for business credit. In other words, the limited liability of the firm no longer applies to this particular credit (Cirmizi et al., 2010). Another related issue is that there may be no clearly established ownership of key commercial assets (such as tools or other essential equipment). It is not unusual for owners to use personal assets for business purposes and business assets for personal or family needs (UNCITRAL, 2020). The closely linked consequence of these characteristics is that in case of default bankruptcy, the entrepreneur will often face personal as well as corporate insolvency (Cirmizi et al., 2010; Cumming, 2012), and if there is no sound personal insolvency regime then the business debts stay with the debtor for an undefined future period. This is stressed in the literature, showing that while the personal guarantee of a firm's owner might encourage a level of financial discipline, in countries without a personal bankruptcy framework a single business failure could doom an owner to a lifetime of outstanding debt (Uttamchandani & Menezes, 2010) and effectively prevent them from re-entering the market as a seasoned entrepreneur (Armour & Cumming, 2005).

What challenge does this cause in an insolvency situation? Existing standard business insolvency regimes usually restrict insolvency proceedings to the business debts of a distinct business entity, and do not comprehensively address the intermingled business and personal debts usually involved in the insolvency of IMSEs. As pointed out by the international experts, individual entrepreneurs may be treated as individual defaulters and be subject to personal insolvency frameworks where such frameworks exist. The latter may not provide temporary protection from creditors, nor allow for debt restructuring procedures and discharge. Where discharge is available for individual entrepreneurs, a long waiting period before discharge may apply, leaving full personal liability for many years after the liquidation of the business. Heavy penalties, including limitations on freedom of movement and other personal restrictions, may also apply (UNCITRAL, 2020). The results of empirical research show that the lack of a fresh start with restrictions on the rights of debtors and a lack of protection of their personal assets are associated with both a lower likelihood of being engaged in a start-up and a lower likelihood of high aspirations towards entrepreneurship in particular (Estrin, Mickiewicz, & Rebmann, 2017).

So, this question of blurring between assets and liability is the main issue to be addressed by insolvency framework aiming to include the perspective of the small business and construct a regime that would effectively handle the situation of the distressed small business.

2) The second specific characteristic of IMSEs is the overlap of ownership, control, and management functions.

The separation between the ownership and the management of IMSEs is blurred in contrast with larger firms with professional management bodies. This feature affects access to insolvency proceedings. Many IMSEs have a centralised management model in which ownership, control, and management overlap (usually within a family) (UNCITRAL, 2020). This causes challenges in times of financial distress because small entrepreneurs fear the

risk of losing control over their business. Empirical research shows that limitations on the entrepreneurs' control over the firm in insolvency proceedings, such as an automatic stay on secured assets and the mandatory removal of management, are associated with a lower likelihood of individuals entering high-aspiration entrepreneurship, which suggests that such provisions should be avoided (Estrin et al., 2016). An owner may also hide a financial crisis out of fear of damaging a good commercial name, relationships with employees, suppliers, and the market, or disrupting existing lines of credit (UNCITRAL, 2020). IMSEs are most often managed by the owner and not a professional manager in contrast to larger enterprises, and may not have the financial information required for an application to commence insolvency proceedings. Because of these features, IMSEs encounter specific difficulties in financial distress, which their bigger counterparties would not usually face.

3) The third specific characteristic of IMSEs is the lack of assets in situations of financial difficulty, and their related challenges due to limited access to insolvency in general, and to restructuring specifically.

Given that most IMSEs' lending is secured by real estate or a personal guarantee, banks have a strong incentive in the event of a loan default to enforce the guarantee or initiate foreclosure to realize the security and collect proceeds (Bergthaler et al., 2015). Unencumbered assets of IMSEs are usually of little to no value for distribution to unsecured creditors. As a result, those creditors may not be willing to invest the time and resources for the resolution of IMSEs' financial difficulties, because the costs of their participation in those efforts may outweigh the returns. Hold-outs by secured creditors and the disengagement of unsecured creditors jeopardise the chances of successful debt restructuring negotiations and the reorganization of viable IMSEs, leaving liquidation as the only option (The World Bank, 2017). Additionally, due to the lack of (sufficient) funds in the insolvency estate, IMSEs may be ineligible to apply for insolvency in some jurisdictions, or insolvency proceedings may be terminated after their commencement in other jurisdictions (UNCITRAL, 2020). Burdened by unresolved financial difficulties and old debt, IMSEs may be discouraged from taking new risks, become trapped in a cycle of debt, or be driven to the informal sector of the economy (Mokal et al., 2018).

In can be concluded that the traditional assumption among insolvency policy makers for a long time has been that small businesses usually act as larger businesses, only on a smaller scale. We have showed that the size and nature of small businesses distinguishes them from their larger counterparts, creates special challenges in times of financial distress, and requires, inter alia, some very different approaches to insolvency policy.

In order to be effective, insolvency frameworks should address the specific needs of financially distressed small business throughout the entire insolvency framework, focusing on specific points where: access can be improved and made less costly; the question of intermingled assets, liability, and a fresh start will be dealt with; and where IMSEs can be encouraged to seek early advice on how to address their financial difficulties.

3. Do existing international standards on the effectiveness of insolvency frameworks take into account the specifics of IMSE insolvency?

3.1. The international standards on effectiveness of insolvency frameworks – general considerations

Determining the effectiveness of an insolvency system requires the evaluation of both quantitative and qualitative elements. As insolvency systems seek to achieve complex objectives, the characteristics and the volume of data required to assess their effectiveness can be significant. In addition, there are features of the system that need to be assessed qualitatively. For this reason, the analysis of insolvency systems relies on the interplay of standards, indicators, and data (Garrido et al., 2019).

In this chapter, we will verify whether the existent international initiatives and instruments that provide guidelines for countries wishing to assess the effectiveness of their current insolvency frameworks, or wishing to steer their reforms towards designing well-functioning insolvency regimes, take into account the specific needs of IMSEs.

For many years, scholars and experts have sought to describe the best framework for insolvency. While there is no universal model or blueprint for optimal insolvency systems worldwide, there are several important standards elaborated on at the international level that reflect best practices endorsed by the international community and underlie what constitutes a sound insolvency regime. These standards represent the consensus of international bodies on the core features of legal or regulatory systems. The two primary internationally recognized benchmarks jointly acknowledged as international standards for insolvency regimes are The World Bank's "Principles for Effective Insolvency and Creditor Regimes" (The World Bank, 2016) and the UNCITRAL's "Legislative Guide on Insolvency Law" (UNCITRAL 2004–2013; Consolo, Malfa, & Pierluigi, 2018), based on which the World Bank has built the Resolving Insolvency indicator in its most famous product: Ease of Doing Business rankings. The UNCITRAL itself does not provide for specific evaluation criteria and indicators, but the World Bank relies on its research when creating and refining the system of Resolving Insolvency indicators.

Additionally, some other major international players have also provided policy recommendations towards reforms that target insolvency frameworks: the IMF report of 1999 discussed the major policy choices to be addressed by countries when designing insolvency systems (IMF, 1999); OECD compiled a new database on insolvency framework reforms with the 13 OECD indicators of insolvency frameworks (OECD, 2018b); and the EU adopted the new Directive on restructuring and insolvency 2019/1023, which aims at achieving common standards on early restructuring across EU Member States (Directive 2019/1023, 2019).

Next, we will more closely review whether these initiatives take into account the specific characteristics of IMSEs when constructing their guidelines on the evaluation of the effectiveness of insolvency framework.

3.2. The World Bank Principles and Resolving Insolvency indicators system

One of the main data sources on insolvency frameworks is the World Bank's Ease of Doing Business index with its specific Resolving Insolvency indicator that not only provides a snapshot of a country's relative position, but also monitors its evolution from one year to the next and allows for an evaluation of the level of achievement.

Even though the Ease of Doing Business Index is formally a non-coercive reporting exercise, and may not always accurately reflect appropriate regulation, its existence has influenced governments around the world to change their economic and regulatory policies. By benchmarking, and especially by ranking, the World Bank intentionally exerts competitive social pressure on states. Plausible observational evidence demonstrates an average global correlation between publicizing the rankings, bureaucratic adaptations responding to the rankings, and the acceleration of actual policy reforms. One investor survey experiment clearly showed that international investors may also be influenced by a state's Ease of Doing Business rankings (Doshi, Kelly, & Simmons, 2019). The Doing Business index is often cited in the agendas of legislative powers in justifying insolvency reforms with the aim of improving the country's position in the World Bank doing business ranking (e.g., India, Lithuania, Portugal, Yemen, Russia, and many others as seen from the World Bank Group reports). This ranking focuses on regulatory issues and their importance for growth. The close relationship between improving the legislative framework and growth underpins an important set of developments that has been repeated since the beginning of this century. The seminal work by Djankov, McLiesh, and Ramalho (2006) confirms this association (Estevao, Lopes, Panela, & Soares, 2020).

The Doing Business Index, launched in 2002, aspires to provide evidence-based objective measures of regulations applied to small and medium enterprises through their life cycle. As the Doing Business report explains in its own

description: "By gathering and analysing comprehensive quantitative data to compare business regulation environments across economies and over time, Doing Business encourages countries to compete towards more efficient regulation; offers measurable benchmarks for reform" (Žylius & Basheka, 2014; website of Doing Business: https://www.doingbusiness.org/en/doingbusiness). The Doing Business Resolving Insolvency indicators aim at measuring the efficiency and quality of insolvency frameworks around the world. These indicators are not static, and the evaluation system is evolving with each evaluation period.

At the beginning the Resolving Insolvency indicators focused only on outcome-based indicators, capturing the efficiency of insolvency proceedings through the set of recovery rate indicators: the time, cost, and outcome of insolvency proceedings, and how much creditors would recover at the end (i.e., the recovery rate). In 2015, Doing Business introduced an important change in the methodology of indicators for Resolving Insolvency. Besides measuring the recovery rate, it now also tests whether each economy has adopted internationally recognized good practices in the area of insolvency. A new indicator, the strength of insolvency framework index, measures good practices in accordance with the principles developed by the World Bank and the UNCITRAL – the World Bank's "Principles for Effective Insolvency and Creditor/Debtor Regimes" and UNCITRAL's "Legislative Guide on Insolvency Law".

The purpose of the change in the methodology was to provide a more complete and balanced view of the insolvency framework in each economy by addressing both the quality of the law and the efficiency of its implementation – in other words, to focus on the effectiveness instead of just efficiency. Additionally, while the previous methodology focused mainly on secured creditors, the new index widens the reach of the set of Resolving Insolvency indicators to debtors and unsecured creditors (The World Bank, 2014).

So currently, country rankings are based on performance with respect to two equally weighted sub-indicators (50:50):
1) Outcome-based indicators: the recovery rate, based on the time, cost and outcome of insolvency proceedings based on a stylised case study;
2) Strength of Insolvency Framework Index (introduced in 2015), based on four other indices: commencement of proceedings index; management of debtor's assets index; reorganization proceedings index; and creditor participation index.

In order to answer if the needs of IMSEs are being taken into account when evaluating the effectiveness of insolvency regimes applying the Doing business methodology, we need to consider the basis for both of these sub-indicators.

Regarding the methodology of the outcome-based indicators, it is necessary to mention that the case study is used to derive the outcome based (de facto) indicators. This has both advantages and disadvantages. On the positive side, it is a direct attempt to gauge the average time and cost of insolvency proceedings given that survey respondents typically find it difficult to give an exact answer to a general questionnaire without details on the complexity of the individual case (The World Bank, 2014).

From the other side, these answers depend on the situation at hand: general assumptions used as a basis for this methodology are generated based on answers related to one specific situation and one concrete type of subject. So, what are these general assumptions, and do they cover the situation of IMSEs? There are 2 groups of assumptions in the case: 1) assumptions about the business; and 2) assumptions about the case. From the assumptions about the business we can see that the case is based on the example of a firm (a hotel) with more than 200 employees, 50 suppliers, and solid assets (real estate), and has a professional general manager and a market value of operating as a going concern, of 100 times income per capita or US$200,000, whichever is greater (The World Bank, 2014). So, if compared with the specific characteristics of IMSEs as described above, these business assumptions are based on an example which clearly does not reflect the situation of most IMSEs.

Firstly, it only covers corporate insolvency and therefore the individual entrepreneurs are not covered by it at all. Second, all of these characteristics of the firm are way above the threshold of the micro and small business, and do not reflect their specific characteristics which require different solutions. Namely, IMSEs in most cases are small family businesses with intermingled personal and business assets led by their owner and not a professional manager, while the case example is clearly a medium-sized professionally led enterprise.

Accordingly, the results acquired by using the methodology related to the outcome-based indicators of the World Bank Doing business Resolving Insolvency indicator do not cover the situation of IMSEs, and therefore cannot per se be transferred and applied to the situation of IMSEs, nor to the situation of individual entrepreneurs who are not covered at all, nor to the situations of micro or small businesses.

Regarding the methodology of the Strength of Insolvency Framework Index it needs to be stressed that, after going through all four indices (commencement of proceedings index, management of debtor's assets index, reorganization proceedings index and creditor participation index) and their components, the conclusion could be made that they do not distinguish between various types of debtor's and concern only the general insolvency questions relevant to larger firms (having access to the proceedings, active participation of creditors, etc.). They do not take into account the specific questions relevant to IMSEs, especially the so-called blurred line between the corporate vs. non-corporate distinction of assets and liabilities (see Berkowitz & White, 2004; Cumming, 2012).

We can conclude that in the current version of the World Bank Resolving Insolvency indicator system based on international good practice there are no guidelines on how to construct an effective insolvency regime that would cover the specific needs of IMSEs.

3.3. The OECD indicators for evaluating insolvency regimes

Another influential international organisation that works on establishing evidence-based international standards and finding solutions to a range of social, economic, and environmental challenges is the OECD. For many years, the OECD has developed a variety of indicators that measure the regulatory barriers for starting businesses and competition, allowing for the comparability of results across countries (Koske, Wanner, Bitetti, & Barbiero, 2015). However, a similar system of indicators tackling the regulatory barriers to the last cycle of a business's life – firm exit, or in other words insolvency – has been absent.

To fill a gap and provide complementary insights to those of the World Bank indicators system, particularly in regard to the identification of detailed policy-level reform needs, in 2018 the OECD designed and constructed a new set of cross-country indicators of insolvency regimes (McGowan & Andrews, 2018) via its Going for Growth framework. The choice of questions and the quantitative coding of the potential responses to each question were based on the main conclusions of the theoretical and empirical literature on the links between insolvency regimes and economic growth. The report, which formed the basis for the system of indicators, makes reference to the World Bank system, stating that the available cross-country indicators of insolvency regimes (e.g., World Bank Doing Business) have a number of drawbacks which make it difficult to identify the contribution of insolvency regimes to productivity performance (McGowan & Andrews, 2016). To fill the gaps in the existing indicators, the OECD presented new cross-country policy indicators on the effectiveness of insolvency regimes.

So does this OECD framework take into account the specific characteristic and needs of distressed IMSEs?

The OECD distinguishes 4 groups of factors to be considered when evaluating the effectiveness of insolvency regimes, and the indicators, in contrast to the World Bank Resolving Insolvency system, cover not only corporate but also personal insolvency.

Specifically, the four main insolvency indicators (divided into 13 sub-indicators) are:

- A. Treatment of failed entrepreneurs: in other words, the availability of a fresh start for failed entrepreneurs with respect to two features: time to discharge; and exemptions of their personal assets from insolvency proceedings;
- B. Prevention and streamlining: three mechanisms that aid prevention and streamlining: early warning mechanisms, pre-insolvency regimes, and special insolvency procedures for SMEs;
- C. Tools related to actual restructuring: five features: the ability of creditors to initiate restructuring, the availability and length of stay on assets, the priority order of claimants (such as government or employees), the treatment ("cram-down") of dissenting creditors, and the incumbent management;
- D. other factors, such as: the degree of court involvement, provisions distinguishing between honest and fraudulent bankruptcies, and the rights of employees (OECD, 2018b).

As we see, the OECD indicators already tackle many questions relevant to IMSEs.

The first key dimension is the treatment of failed entrepreneurs, which is of paramount importance for IMSEs.

The most up-to-date research on the association between the effectiveness of insolvency regulations and entrepreneurship (Fu, Wennbertg, & Falkenhall, 2020), along with cross-country evidence compiled in the OECD Going for Growth interim report (2018), suggests that in particular a lengthy time to discharge can discourage entrepreneurship. The availability of a "fresh start" has been found to foster the growth of productivity via higher incentives for entrepreneurship and experimentation by: i) increasing firm entry (Cumming, 2012); ii) providing failed entrepreneurs with a second chance to apply their experience and lessons learnt to ensure the growth of their new businesses (Burchell & Hughes, 2006); and iii) attracting better quality entrepreneurs – i.e., individuals with higher observed human capital (Eberhart, Eesley, & Eisenhardt, 2016).

The OECD indicator assumes that a lengthier time to discharge is detrimental to the growth of productivity, and hence is given a higher ("worse") value. Threshold values of one and three years are adopted for scoring, with the worst score given to a time to discharge above three years. This is also in line with the EU position of limiting discharge periods in the EU to a maximum of three years for honest entrepreneurs.

The second important position linked with IMSEs can be found under the sub-indicators of the indicator "Prevention and streamlining features", namely "Special insolvency procedures for SMEs". On the one hand, this calls for the specific forms of business to be taken into account, which is good for IMSEs, but conversely this sub-indicator does not distinguish between IMSEs and medium-sized enterprises that, as we previously clarified, are very different from small businesses. The indicator gives a score only for the existence of special insolvency procedures for SMEs, and does not give any insights into how insolvency framework should be designed in order to take into account the specific characteristics and needs of IMSEs.

Under the third indicator of "Restructuring tools", the OECD summarises the general principles related to sound restructuring regimes (such as the possibility for creditors to initiate restructuring and the possibility of management not to be dismissed during restructuring, which is important for IMSEs as well as for all other forms of business) and does not indicate any specifics related to IMSEs. For example, often in the literature the question of the impeded access of IMSEs to these procedures in general is raised, whether due to the lack of resources to finance such proceedings, to engage an insolvency professional etc. (Mokal et al., 2018).

The fourth indicator "Other design features" again shows some relevance to distressed IMSEs, especially its sub-indicator related to the degree of court involvement. Court involvement costs and this financial burden could

impede access of IMSEs to insolvency procedures, due to a lack of assets to cover the associated fixed costs (Bergthaler et al., 2015).

In conclusion, the OECD indicators partially take into account the specifics of the IMSEs, but provide no coherent system for the elements to be included into insolvency framework in order to have an effective insolvency regime for IMSEs. Still, this is currently the most important available tool, giving at least some initial guidance to countries on how to construct effective insolvency framework that can respond to the specific needs of IMSEs. These indicators also allow for cross-country comparisons of certain features of the design of insolvency regimes regarding how they treat financially distressed IMSEs, and give future insights for policy reforms in this area.

3.3. Other standards and initiatives

As already mentioned, the IMF also targeted the issue of effective insolvency framework with its "Guidelines for Orderly and Effective Insolvency Procedures" (IMF, 1999), which was primarily concerned with the application of insolvency laws to enterprises rather than individuals. This report did not distinguish between large and small enterprises and, before formulating general guidelines, clearly stated that a number of the issues discussed may only be of particular relevance to a relatively large enterprise that has a number of creditors with divergent interests. Due to the limited scope of this report, we can conclude that there are no guidelines in the IMF report on how to construct an effective insolvency regime that would take into account the specific characteristics and needs of IMSEs.

We can find some general ideas on the importance of IMSEs in its later report from 2015—"Tackling Small and Medium Sized Enterprise Problem Loans in Europe" (Bergthaler et al., 2015)—which presumed that, based on cross-country experience with distressed small and medium sized enterprises (SMEs), a comprehensive strategy including insolvency reform targeted at SMEs is needed. Insolvency regimes should close the gap with international best practice for rapid pre-pack approvals, "fresh start"/debt discharge, and debtor-in-possession financing. As we have outlined, these proposed solutions address the whole business sector in general but are not specifically tailored for IMSEs.

At the EU level, a number of initiatives were developed targeting the regulatory framework for small businesses, including the Small Business Act 2008 which outlines a set of recommendations based on cross-country experience and good practice, but does not specifically focus on insolvency issues (European Commission, 2008). The most important achievement at the EU level is the new Directive 2019/1023 of the European Parliament and of the Council of 20 June 2019 on preventive restructuring frameworks, on the discharge of debt and disqualifications, and on measures to increase the efficiency of procedures concerning restructuring, insolvency, and discharge of debt, and amending Directive (EU) 2017/1132 (Directive on restructuring and insolvency), which aims at enhancing rescue culture in the EU and encouraging entrepreneurship by avoiding the stigmatization of business failure and providing the opportunity for a second chance. However, its approach was rightly criticized in the literature for not devoting enough attention to micro, small, and medium sized enterprises (and following, not taking into account the specifics of IMSEs), and clearly designing most of its provisions for larger corporations (Madaus, 2017; Mokal et al., 2018). Additionally, the EU constructed the information tool "EU Justice Scoreboard", which aims at helping the EU to achieve more effective justice and provides comparable data on the independence, quality, and efficiency of national justice systems. This scoreboard, however, does not focus specifically on insolvency problems and, as is almost self-explanatory, does not provide EU Member States with concrete standards and indicators for the evaluation of the effectiveness of insolvency frameworks in relation to the specifics of IMSEs.

In conclusion, whilst EU initiatives may have some important implications for IMSEs they are not tailored specifically to IMSEs, and do not provide countries with the standards or indicators of best practice that might enable them to guide reforms aimed at improving the effectiveness of insolvency framework for IMSEs.

The overall conclusion based on the analysis of the existing international initiatives and instruments is that currently there is no comprehensive international guidance which could stimulate and steer countries to improve the effectiveness of their insolvency frameworks in a way that would respond to the needs of the majority of businesses – IMSEs.

There is a need to create a more all-encompassing framework for the evaluation of the effectiveness of regimes of insolvency law applicable specifically to IMSEs. The international community is becoming aware of this, and has already initiated some important steps in order to tackle this problem. The most important work currently in progress is the UNCITRAL work on a "Draft Text to Simplify Insolvency Regime Proceedings" (UNCITRAL, 2020), which specifically targets the needs of financially distressed small business. From the agendas of the World Bank, it can also be seen that a new objective for its Working Groups to prepare a joint standard setter together with UNCITRAL in the area of insolvency for small businesses has been introduced (The World Bank, 2017). If it succeeds with outlining a specific set of indicators related to small businesses, then this would be a major reform stimulus for many countries aiming at improving the effectiveness of insolvency frameworks for IMSEe.

5. Conclusions

This research argues that one of the key objectives of an effective insolvency framework should be to provide solutions on specific issues arising from the insolvencies of IMSEs, such as the blurred distinction between the assets and liabilities of the business and those of the owner, the overlap of ownership, control, and management functions, concerns over stigmatization, resource poverty, and the disengagement of creditors.

The analysis of the existing international guidelines that deal with the evaluation of the effectiveness of insolvency frameworks shows that current good practice guidelines and indicators either do not cover issues that are important for IMSEs at all or are tackling only some of them in a more general manner. Specifically, countries aiming at improving their World Bank Doing Business ranking in relation to the Resolving Insolvency indicator should be aware of its current limitations regarding the specific needs of IMSEs in times of financial distress. The OECD indicators of insolvency regimes are currently the most suitable tool for providing some initial guidance on how to construct effective an insolvency framework that adequately addresses at least some of the specific needs of IMSEs.

Despite these positive steps in initiating the reforms aimed at targeting the needs of financially distressed IMSEs, there is a need for a more comprehensive approach toward IMSEs in financial distress which would stimulate and steer countries to improve the effectiveness of their insolvency frameworks in a way which would respond to the needs of the majority of businesses: IMSEs, and to encourage entrepreneurship as a consequence.

ATTITUDES TOWARDS ARTIFICIAL INTELLIGENCE IN THE AREA OF PERSONAL FINANCIAL PLANNING: A CASE STUDY OF SELECTED COUNTRIES [*]

Krzysztof Waliszewski [1], Anna Warchlewska [2]

[1,2] *Poznań University of Economic and Business, al. Niepodległości 10, 61-875 Poznań, Poland*

E-mails: [1] krzysztof.waliszewski@ue.poznan.pl; [2] anna.warchlewska@ue.poznan.pl

Abstract. The financial sector's focus on simplifying decision-making processes, maximally shortening procedures via cooperation with the fintech industry, robotisation and the use of artificial intelligence are a response to market needs and becoming an important element of how financial service groups compete on the market. The theory of consumer behaviour assumes that consumers have needs that they will hierarchise, and that they will make choices to maximise their own satisfaction. The purpose of the article is to diagnose the sociological and economic determinants underlying consumer satisfaction in terms of planning personal finances using modern technologies. Comparisons of international data were conducted via quantitative analysis of robo-advice using Mann-Whitney U tests, the Chi-square test and Spearman's rho correlation. The survey results show that the majority of socioeconomic characteristics of households are statistically significant when considering satisfaction with robo-advisory financial services and spending analysis, as well as with artificial intelligence suggesting improvements. This study is a contribution to the literature on consumer behaviour in the modern world.

1. Introduction

The effectiveness of using artificial intelligence (Belanche et al. 2018) in various aspects of the economy has been a topic of discussion for many years now. The speed with which users implement and adapt new technological solutions depends on the level of sophistication offered by financial services in a given country. Each financial institution struggles with data overload and the problem of processing and selecting the most relevant. Thanks to technology, robotisation and artificial intelligence, it becomes possible to personalise customer service and switch to remote service channels.

The application of modern financial solutions not only serves to minimise the costs associated with employment, but also to target action on the complex problems faced by customers. Robotics and artificial intelligence (Xie, 2019) both significantly influence the financial industry, as the technology used there is a key element in the strategy of banks and emerging financial entities (Baker & Dellaert 2017; Jung et al. 2018). Replacing traditional consultancy services with innovations, especially at the beginning, is not met with much enthusiasm, mainly due to the novelty factor, competition, fear and lack of knowledge (Belanche at al. 2018).

The global landscape of innovation is undergoing comprehensive transformation due to the growing importance of intangible investment. The fintech concept (Schueffel 2016; Gai et al. 2018; Das & Ali 2020) currently transcends electronic banking and consumer digitisation services and focuses on the development and implementation of innovative financial instruments to meet the financial requirements of the end-users. Digital technologies (Skinner 2018; Jagtiani & Kose 2018; Tanda & Schena 2019) and their impact on consumer decisions currently stand at the forefront of international consumer policy discourse (Zopounidis et al. 2018; Bhatia, 2019). The use of modern technologies presents a clear opportunity to accelerate the transformation of the banking sector and give users greater control over their finances and increase the value of their investments. Asset management support technologies may play a new and promising role in supporting financial decisions that involve analysing decisions in circumstances of uncertainty and a huge diversity of possible decisions. The impact of modern financial technologies on data transfer and security, consumer privacy, as well as the responsibility of financial service providers on online platforms and digital consumer education are just some of the hot topics of our times (Świecka et al. 2020; Thorun & Diels 2020).

One form of automated financial consulting is robo-advice – defined as an automated investment platform that uses quantitative algorithms to manage investors' portfolios and accessible to clients online. Robo-advisors differ from existing online investment platforms or online brokerage with respect to two different conceptual levels: customer assessment, and customer portfolio management (Beketov et al. 2018; Jung et al. 2018). The solution is based on advanced algorithms using artificial intelligence and tools for analysing large data sets. The robo-advisor (online software) provides vital financial advice to their clients in a cost-effective manner with moderate to minimal human interventions (Balwani et al. 2019). Emergence of financial technologies ecosystem was preceded by three waves of technological disruptive changes: electronic payments, blockchain and cryptocurrencies, and artificial intelligence. The concept of artificial intelligence in the financial sector centers on devices that can interpret and understand tasks and take action to complete those financial tasks. For example, the devices might be robo-advice, digital brokers, or assorted devices used in trading, tax management, and trade decision making. Artificial intelligence offers a high degree of automation and efficiency improvements, which are most apparent in investment platforms and portfolio management (Palmiéa et al., 2020).

Robo-advisors have emerged from the entwinement of two strands of history represented by investment theory and AI-technology during the latter part of the 20th century. The leading robo-advisory models founded in today's AI-driven technological environment are mostly based on Modern Portfolio theory (MPT), based on an optimal portfolio for a given investor's risk preference. Therefore, behavioural finance is considered as one of the most realistic representation of financial markets and investor behaviour, which might eventually replace MPT as the paradigm of choice. This shift to behavioural finance received a further boost in 2017, with recent developments in AI-based machine learning, which have built the momentum through the possible combination of two investment philosophies (Shanmuganathan 2020).

Research into the implementation of robo-advisory solutions in practice is limited (D'Acunto et al., 2019). Literature and reports predominantly focus on technical, legal and market forecasting issues (Jl, 2017; Mordor Intelligence 2017; Netscribes 2018; Glaser et al. 2019; EIBIS 2020), excluding the use of robo-advice in personal

finance planning. The use of robo-advice has come under the microscope in the USA and China. Over one million Bank of America customers use the services of a chatbot (named Erica) to submit basic financial inquiries (Rosman, 2018). Another example of the practical use of modern technologies is the Bank of Tokyo (Marinova et al., 2017), where a banker-humanoid (named Nao) accompanies the client during a standard visit to the bank. Banks and entities from the fintech industry seek to popularise robo-advice services, claiming that they offer a competitive advantage. It is worth emphasising that the size of the market is expanding, and robo-advisers manage approximately USD 880,000 million of assets and have noted an annual increase of 30% (Statista.com 2019). Analyses conducted thus far (Lundahl et all 2009; Sabri 2011; Bhatnagar 2016; Iriobe & Oyinlola 2017) do not relate directly to an assessment regarding which socio-demographic traits – from a statistical point of view – may influence the level of satisfaction experienced by customers (Kim & Lim 2010) with the use of modern technologies in personal finance in terms of robo-advice and the monitoring of spending habits.

Progress in information technology (IT) and information systems (IS) provides firms with more options for replacing or supplementing personal service provision with self-service technologies (SST). Many of these technologies provide decision support to consumers either as their main purpose (apps, information terminals) or as a fringe benefit (self- scanning) (Djelassia et al., 2018). Robo-advice is an example of customer self-service technology (SST). SST is applicable, among others, in retail and financial services as a customer-centric strategy and fosters loyalty, trust, or word-of-mouth communication (Taillon & Huhmann 2017). One of the prominent benefits noted by customers is that self-service allows customers to have greater efficiency in a transaction and so they forego the full service option and purchase online (Collier & Barnes 2015).

The subject of Technology readiness (TR) of SSTs is also discussed in the literature, i.e. the customer's psychological willingness to accept new technologies. TR comprises four dimensions: innovativeness, optimism, discomfort and insecurity. Service providers introduce self-service technologies to increase productivity and efficiency and to offer customers access to services via new and convenient channels, thereby better meeting customer demands and boosting their satisfaction. The impact of TR on customers can be investigated by (1) attitude towards using SSTs, (2) adoption of SSTs, i.e. actual usage and (3) response to the firm in terms of perceived service quality, satisfaction and loyalty to an SST (Liljandera, Gillberg, Gummerus, Rie 2006). Other dimensions of TR are innovativeness and optimism and they have a positive impact on the customers' decisions to use self-service technologies while discomfort and insecurity have a negative impact (Gelderman et al. 2011). SST service quality can be measured by examining many dimensions including functionality, enjoyment, security, assurance, design, customisation and convenience. The quality of self-service technology in retail banking services consists of four elements – consistency, dependability, timeliness and technology – based on two popular dimensions, which are reliability and responsiveness and their influence on customer satisfaction (Iberahim, et al. 2016). The literature also discusses the positive relationship between a self-service technology investment and solid financial performance (Hung et al. 2012). Buyers' continued usage of SSTs depends on their acceptance of the technology and their satisfaction with service delivery based on two different lines of research: technology acceptance and service/relationship marketing. Buyers who are satisfied tend to continue their usage, whereas dissatisfied buyers withdraw (Erikkson & Nilson 2007). There are no studies on socio-economic factors affecting the satisfaction of using self-service services based on the example of robo-advice. This indicates the existence of a research gap, which the results of the study and their analysis presented in the article intend to fill.

One of the main theories related to the customer self-service process is that of resource matching (Anand & Sternthal 1999) and its further theoretical development within the field of efficiency (Collier & Kimes 2012; Zhu et al. 2007). This theory is a reference point for environments where performance is the key goal. Unfortunately, it cannot be fully applied to analyses regarding remote consumer service channels in the financial sector, as it is not

appropriate for the dynamics of action and operations performed independently. The theory of consumption values focuses on efficiency (which better describes consumer behaviour in the digital financial services market), explaining why consumers decide to buy (Sheth et al. 1991). Financial service providers using remote applications strive towards increased efficiency, performance and diversification of communication channels (Liljander et al. 2006; Collier & Barnes 2015; Iberahim et al. 2015). Customer self-services enables a new service model to be created that bases its assumptions on the equal involvement of investors and bidders in the financial management process and can influence the establishment of long-term relationships between the parties involved (Djelassi et al. 2018). Most financial institutions do not take advantage of customer self-service potential because they base their assumptions on an incomplete business model in the area of remote service. Remote financial management support services are focused on the speed of response to reported needs, reducing service time, convenience for customers and lowering costs for the service provider (Boon-itt 2015). Innovation in finance may go hand in hand with consumer discomfort arising from lack of control over modern tools, uncertainty of their knowledge and skills, lack of confidence in technology and a sense of technological overwhelm (Parasurman 2000).

One of the objectives of using modern technologies is to support consumer decision-making processes and adapt modern financial services to evolving needs (Buettner 2017; Nitin et al. 2019). Robo-advice facilitates management by providing potential investors with investment guidelines regarding the benefits of investing. Implementing a new path of communication with the recipient requires in-depth research into consumer behaviour, knowledge of which is necessary not only when it comes to understanding purchasing decisions, but also in order to create tailor-made products and predict the future evolution of customers' decisions (Mazurek, Maz 2019). Analysis of consumer attitudes significantly affects preferences and further predictions based on the personality of the user (Blackwell et al. 2005). The assessment of alternatives in the financial decision making process (Beckett et al. 2000) is a multi-stage process, which consists of (a) forming opinions on possible methods of satisfying needs, (b) shaping attitudes towards them and (c) establishing a purchase. This scheme draws on previously accumulated information and experience. Therefore, the challenge is the diagnosis of which determinants may be significant to the consumer in order to shift financial management towards robo-advice. The implementation of modern technologies in the process of personal finance management offers a number of challenges in the area of data circulation and analysis, digitisation and the automation of manual processes, as well as big data architecture.

The purpose of the article is to diagnose the sociological and economic determinants underlying consumer satisfaction in terms of planning personal finances using modern technologies. The paper is organised as follows. At the beginning the article presents the research methodology, after which the authors outline the main results of their worldwide survey. Subsequently, the discussion of the results is shown, whereupon the authors conclude by listing limitations and offering future research options.

2. Methodology

The statistical material used in the article stems from the *ING International Survey – New Technologies 2019*. This online survey was carried out by Ipsos from 30 January to 11 February 2019. Sampling reflects gender ratios and age distribution, selecting from pools of possible respondents furnished by panel providers in each country. European consumer figures are expressed as an average, weighted to take the varying populations of the countries into account. 14,824 respondents from 15 countries (Austria, Belgium, Czech Republic, Germany, France, Italy, Luxembourg, Netherlands, Poland, Romania, Spain, Turkey, United Kingdom, USA, Australia) were involved in

the survey. The article uses data for Poland made available directly by ING Bank Śląski economists for scientific purposes. 14,824 respondents were surveyed, whose descriptive statistics are presented in Table 1.

Table 1. Descriptive statistics of the studied population (N = 14,824)

Source: ING International Survey – New Technologies (2019).

Regarding the use of modern technologies in personal financial management, the respondents were presented with two statements to evaluate their level of satisfaction:
1) I would be happy for a computer program to make investment decisions on my behalf.
2) I would be happy for a computer program to analyse my spending habits and recommend improvements.

The respondents responded to these statements on a 5-point Likert scale: 1 – totally disagree, 2 – disagree, 3 – difficult to say, 4 –agree, 5 – totally agree.

In order to analyse the date, the following statistical methods were employed:
1) The Chi-square test for independence: a nonparametric method for testing the relationship between two variables expressed on a qualitative scale. These were socio-demographic variables with 2 questions on a 5-point scale.
2) The Mann-Whitney U test: a nonparametric test for studying the differences between 2 groups. In this case, Poland is compared with each country in turn, and the average acceptance value of robo-advice in terms of qualitative sociodemographic variables (gender, work) was compared in different countries.
3) Spearman's rho correlation coefficient: a nonparametric test used to examine the relationship between two variables expressed on the ordinal scale. Applied to the relationship between the survey and socio-demographic questions that were graded (rated on a scale from the lowest to the highest).

The following research hypotheses were formulated:
H1: There are statistically significant differences between Poland and the other countries analysed (apart from Italy and Spain) in terms of the acceptance of robo-advice for making investment decisions as well as for a computer program to analyse expenditure and suggest improvements.
H2: In most of the countries studied, age is associated with a lower acceptance for a computer program to make investment decisions, analyse expenditure and recommend improvements.
H3: In most countries, the willingness to allow a computer program to make investment decisions – along with the willingness for a computer program to analyse spending habits and recommend improvements – is proportional to the number of people in the household.
H4: Acceptance for a computer to make investment decisions, analyse expenditure and recommend improvements is inversely proportional to age.

H5:   Most countries feature statistically significant differences between men and women in terms of accepting robo-advice for investment and there is no difference in terms of accepting a computer program to make expenditure analysis and recommend improvements (apart from Germany, the Netherlands and Turkey).

H6:   In most countries there are differences between working and non-working people in terms of accepting robo-advice for investment or as a means of analysing expenses and suggesting improvements.

3. Research background

Table 2 presents the most significant robo-advisor parameters in Europe. Assets under management in Europe amounts to USD 49,471m in 2020 in the robo-advisor segment. Assets under management are expected to show an annual growth rate (CAGR 2020-2023) of 35.2% resulting in a total amount of USD 122,312 million by 2023. In the robo-advisor segment, the number of users is expected to amount to 4,005.1 thousand by 2023 from 2,173 thousand in 2020. The average assets under management per user in the robo-advisor segment amounts to USD 22,767 in 2020 and is expected to grow to USD 30,539.

Table 2. Robo-advisors in Europe

Key characteristics	2017	2018	2019	2020	2021	2022	2023
Assets under Management (in million USD)	7 365,0	15 925,0	30 052,0	49 471,0	72 689,0	97 626,0	122 312,0
Assets under Management Growth (in percentages)	-	116,20	88,70	64,60	46,90	34,30	25,30
Users in thousands	562,90	962,50	1 509,10	2 173,00	2 891,30	3 506,20	4 005,10
Penetration Rate (in percentages)	0,10	0,10	0,20	0,30	0,30	0,40	0,50
Assets under Management per User in USD	13 085,0	16 546,0	19 914,0	22 767,0	25 141,0	27 844,0	30 539,0

Source: Statista.com (2020).
Note: penetration rate is the share of active paying customers (or accounts) from the total population of the selected market (market segment, region) for each year.

Taking into account only the 15 countries studied, assets under management by robo-advisors are presented in Fig. 1. According to data for 2020, the total value of these assets amounted to USD 43,032.0 million projected to rise by 2023 to a level of 106,590.0 million USD. The largest markets were Germany and the United Kingdom, accounting for 32% and 52% of assets under management respectively of all the countries surveyed.

Fig. 1. Assets under Management of robo-advisors in million USD in selected European countries
Source: Statista.com (2020)

Taking into account the users of robo-advisors in the 15 European countries surveyed (Fig. 2), in 2020 there were 1635.00 thousand projected to rise by 2023 to 2867.3 thousand. Most users of this service are in Germany and the United Kingdom, accounting for 27% and 46% respectively of all users among the countries surveyed.
Fig. 2. Users of robo-advisors in thousands in selected European countries
Source: Statista.com (2020)

Fig. 3 and 4 present the structure of answers to 2 questions presented to the respondents. The first question concerned financial robo-advice supporting investment decisions. In the case of the European countries studied, the average of the responses was 18% agree, 21% neither agree or disagree and 61% disagree. Countries with the greatest levels of satisfaction with financial robo-advice include Turkey (30%), Romania (21%), Czech Republic

(20%), UK (19%), Poland (18%) as well as Spain and Italy (17%). For the USA, 22% responded 'agree'. The second question concerned satisfaction a computer program analysing spending habits and suggesting improvements (Fig. 2). For the second question, the percentage of those satisfied was higher than the first. The average 'agree' response for the European countries studied was 38%, and the highest level of satisfaction was indicated by respondents from Turkey (65%), Romania (53%), Poland (45%), Czech Republic (42%), Spain (41%), Luxembourg (35%) and the UK (34%). In the case of the USA, the percentage of respondents indicating satisfaction was the same as the European countries studied and amounted to 38%.

Subsequently, in the first stage of the study, the Poles' opinion on financial robo-advice was compared with the opinion of residents of other countries in this respect. Comparative analyses were performed using a series of Mann-Whitney U tests. Table 3 presents the results of the comparative analyses together with descriptive statistics for opinions on financial robo-advice for making investment decisions by country.

Table 3. Descriptive statistics for opinions on financial robo-advice for making investment decisions by country and the results of comparative analyses via Mann-Whitney U tests

I would be happy for a computer program to make investment decisions on my behalf	M	SD	Z	p	r
Poland	2,35	1,16		-	
Australia	2,11	1,11	4,69	***	0,10
Austria	1,93	1,09	8,87	***	0,20
Belgium	2,11	1,08	4,52	***	0,10
Czech Republic	2,50	1,10	3,54	***	0,08
France	2,09	1,17	5,63	***	0,13
Germany	2,11	1,20	5,20	***	0,12
Italy	2,28	1,18	1,53	0,126n.s.	0,03
Luxembourg	2,01	1,03	5,83	***	0,14
Netherlands	2,12	1,08	4,21	***	0,09
Romania	2,49	1,24	2,35	*	0,05
Spain	2,29	1,19	1,43	0,152n.s.	0,03
Turkey	2,78	1,31	7,43	***	0,17
UK	2,23	1,25	3,21	**	0,07
USA	2,48	1,25	2,11	*	0,05

M – mean, SD – standard deviation, Me – median, Z – U Mann-Whitney statistic, p – level of statistical significance, r – strength of effects, *p<0,05, **p<0,01, ***p<0,001, n.s. – statistically insignificant

The results of the Mann-Whitney U tests proved to be statistically significant, which means that there were differences between Poland and the other countries in terms of acceptance of robo-advice for making investment decisions. Only statistically significant differences between Poland and Italy were not indicated $Z = 1.53$; $p = 0.126$; $V = 0.03$ and Spain $Z = 1.11$; $p = 0.265$; $V = 0.03$.

Countries featuring a higher level of acceptance of investment advice for investments included Turkey, the Czech Republic, Romania and the USA. Other countries indicated a lower rate of acceptance of this advisory function, and the lowest value was found for Austria and Luxembourg. Based on the r strength of effect ratio, it can be concluded that the differences were most marked between Poland and Australia and Luxembourg.

Similarly, by means of a series of multiple comparisons via Mann-Whitney U tests, a study was conducted into whether and how Poles differed from other nationalities in terms of robo-advice given by a computer program for analysing expenses and suggesting improvements.

Table 4. Descriptive statistics for opinions on financial robo-advice in terms of analysing habits related to expenditure by country and the results of comparative analyses via Mann-Whitney U tests

I would be happy for a computer program to analyse my spending habits and recommend improvements	*M*	*SD*	*Z*	*p*	*r*

UK	2,77	1,28	8,10	***	0,18
USA	2,99	1,28	4,12	***	0,09

M – mean, SD – standard deviation, Me – median, Z – U Mann-Whitney statistic, p – level of statistical significance, r – strength effects,
*p<0,05, **p<0,01, ***p<0,001, n.s. – statistically insignificant

All results of the Mann-Whitney U analyses turned out to be statistically significant p <0.001. Therefore, citizens of different nationalities differed in their willingness for a computer to analyse their expenditure. Turkey and Romania featured a higher level of acceptance of robo-advice for spending analysis than Poland. The greatest reluctance to have a computer program give financial advice was expressed by the inhabitants of Austria and Germany.

Next, a study was conducted as to whether acceptance of robo-advice was related in different degrees to sociodemographic variables in Poland and other countries. Spearman's rho correlation analysis was used for variables measured on the ordinal scale. Table 5 presents the results of correlation analyses for the relationship between sociodemographic variables and the acceptance of financial robo-advice for making investment decisions by country.

Table 5. Results of Spearman's rho correlation analysis for the relationship between sociodemographic variables and acceptance of financial robo-advice for making investment decisions by country

I would be happy for a computer program to make investment decisions on my behalf	Age	Qualification	Number of people in the household	Income
Poland	-0,03	-0,02	0,07*	-0,03
Australia	-0,34***	0,09**	0,15***	0,04
Austria	-0,10***	0,05	0,11***	-0,07*
Belgium	-0,18***	-0,04	0,12***	-0,03
Czech Republic	0,00	-0,02	0,04	-0,01
France	-0,21***	0,07*	0,14***	0,01
Germany	-0,23***	0,11***	0,12***	0,06
Italy	-0,10**	0,08*	0,10**	0,08*
Luxembourg	-0,13***	-0,05	0,05	-0,09*

USA	-0,34***	-0,01	0,13***	-0,02

*$p<0,05$, **$p<0,01$, ***$p<0,001$

The results of correlation analyses demonstrate that in most countries age was associated with a decrease in acceptance for a computer program to make investment decisions. In the United Kingdom, the strongest relationship in this respect was $\rho = -0.36$; $p <0.001$, then the USA $\rho = -0.34$; $p <0.001$ and Australia $\rho = -0.34$; $p <0.001$. Furthermore, in most countries, the willingness for a computer program to make investment decisions was proportional to the number of people in the household. In the United Kingdom, the strongest relationship in this respect was $\rho = 0.19$; $p <0.001$.

In the case of countries such as Italy, the Netherlands and Turkey, high acceptance for a computer program to make investment decisions was demonstrated to be associated with higher levels of education and income. It is interesting that the exact opposite relationship occurred in the case of Romania.

UK	-0,37***	0,07*	0,19***	0,10**
USA	-0,31***	-0,01	0,20***	-0,01

*$p<0,05$, **$p<0,01$, ***$p<0,001$

For all the countries studied, correlation analyses revealed that as age increased, the acceptance of a computer analysing expenses and recommending improvements decreased. The strongest relationships in this area were also shown by the United Kingdom $\rho = -0.37$; $p <0.001$, then the USA $\rho = -0.31$; $p <0.001$ and Australia $\rho = -0.32$; $p <0.001$, with Turkey having the weakest $\rho = -0.10$; $p <0.01$. Also in most countries, the number of people in the household proved to be proportional to the willingness for a computer program to analyse spending habits and recommend improvements. This relationship was also the strongest in the United Kingdom $\rho = 0.19$; $p <0.001$ and the USA $\rho = 0.20$; $p <0.001$.

Further analysis indicated that for countries such as Germany, the Netherlands, Turkey and the United Kingdom, high acceptance for a computer program to analyse expenditure was associated with higher education and income levels. Romania is the only case where people with a university degree and higher earnings are less willing to have a computer analyse expenses and recommend improvements.

A study was also conducted as to which countries featured a differentiated level of acceptance of financial advice by gender. For this purpose, comparative analyses were carried out using Mann-Whitney U tests.

Table 7. Descriptive statistics for opinions on financial robo-advice in terms of making investment decisions by country and gender as well as the results of comparative analyses via Mann-Whitney U tests

The results of the Mann-Whitney U tests proved to be significant, which means that the countries analysed do feature differences between men and women in terms of accepting robo-advice for investment. No such gender differences were found in Poland Z = 0.28; p = 0.780; r = 0.01, the Czech Republic Z = 0.91; p = 0.363; r = 0.03, Romania Z = 1.66; p = 0.097; r = 0.05, Spain Z = 1.28; p = 0.199; r = 0.04 or Turkey with Z = 0.10; p = 0.924; r = 0.00. In all other countries, men were more willing than women to have a computer make investment decisions for them, and the largest gender differences were found among the inhabitants of Germany and Austria.

M – mean, SD – standard deviation, Me – median, Z – U Mann-Whitney statistic, p – level of statistical significance, r – strength effects,
*p<0,05, **p<0,01, ***p<0,001, n.s. – statistically insignificant

The results of the Mann-Whitney U test were mostly insignificant, which means that there were no differences between men and women in the analysed countries in terms of acceptance of robo-advice for analysing expenses and recommending improvements. Such differences were only demonstrated for Germany $Z = 3.80$; $p < 0.001$; $r = 0.12$, the Netherlands $Z = 3.59$; $p < 0.001$; $r = 0.11$ and Turkey $Z = 3.79$; $p < 0.001$; $r = 0.12$. In the case of Germany and the Netherlands, men were more likely to have a computer analyse their expenses, while in the case of Turkey, women were more likely to do so. People working (employed or self-employed) were also compared with those not working (at school/at university/retired/unemployed) in terms of their evaluation of financial robo-advice by country.

The results of the Mann-Whitney U tests proved to be significant for the most part, which means that the countries analysed do feature differences between working and non-working people in terms of their acceptance of robo-advice advice for investment. No such differences were found for Poland Z = 0.71; p = 0.477; r = 0.02, Austria Z = 0.68; p = 0.495; r = 0.02, Czechs Z = 0.57; p = 0.569; r = 0.02, Luxembourg Z = 1.70; p = 0.089; r = 0.07 or Romania Z = 1.61; p = 0.107; r = 0.05. In the remaining countries, it was shown that working people were more favourably inclined to robo-advice for investment and the widest differences were found in the case of the United Kingdom.

USA	2,76	1,25	3,17	1,27	5,05	***	0,16

*M – mean, SD – standard deviation, Me – median, Z – U Mann-Whitney statistic, p – level of statistical significance, r – strength effects, *p<0,05, **p<0,01, ***p<0,001, n.s. – statistically insignificant*

The results of the Mann-Whitney U tests again proved to be largely significant, which means that in the countries analysed there were differences between working and non-working people in terms of their acceptance of robo-advice for spending analysis. Such differences were not found in Poland Z = 0.94; p = 0.350; r = 0.03, Austria Z = 1.02; p = 0.309; r = 0.03, Czechs Z = 0.31; p = 0.754; r = 0.01 or Romania Z = 0.42; p = 0.677; r = 0.01. In other countries, working people would be more likely to use robo-advice for spending analysis and recommendations for improvement than non-working people. Here too, the most extreme differences were observed in the United Kingdom.

4. Discussion

Analyses on robo-advice have thus far focused on technical and legal issues, while also attempting to forecast the growth of the robo-advice market (Jl, 2017; Mordor Intelligence 2017; Netscribes 2018; Glaser et al. 2019; EIBIS 2020). This study supplements the research approach with an analysis of how socioeconomic factors impact the use of modern technologies in the process of personal finance management. The study determines the statistical significance and strength of the relationship between the individual socio-demographic characteristics presented by the respondents – such as age, gender, employment, number of people in the household, education, income – and their satisfaction with using modern robo-advice technologies in personal finance and a computer program to monitor spending habits and suggest improvements.

In the authors's opinion, interesting conclusions can be drawn from analysis on the impact of psychological and cultural factors on the use of modern technologies to manage personal finances. For the issue in question, this represents a gap in research.

The study gives the following contribution to the literature on the subject: satisfaction with the use of modern technologies in planning personal finances on the example of robo-advice and home budget control depends on socio-demographic variables - age, (except for the control of the home budget by a computer program), income in the household, education, number of people in the household, forms of professional activity.

The direction that further research needs to take is to diagnose why consumers are more satisfied with the use of a computer program to analyse expenditure than with making investment decisions. The study has provided a rationale for analysing the relationship between personality, temperament, risk aversion, sense of security and style of spending.

5. Conclusion

Based on the empirical material collected, the International Survey – New Technologies 2019 found that the percentage of respondents indicating their satisfaction with using a computer program to analyse spending habits was higher than in the case of responses about the use of a computer program to make investment decisions on behalf of the consumer.

The analysis results of the Mann-Whitney U tests proved to be statistically significant, which means that there were indeed differences between Poland and the other countries in terms of accepting robo-advice to make investment decisions. Only between Poland, Italy and Spain were statistically significant differences not demonstrated. Countries with a higher level of acceptance for robo-advice given for investments included Turkey, the Czech Republic, Romania and the USA. The remaining countries had a lower acceptance rate for this robo-advice feature, with Austria and Luxembourg having the lowest. Based on the r strength of effect ratio, it can be stated that the strongest differences were observed between Poland, Australia and Luxembourg. All the analysis results yielded by the Mann-Whitney U tests proved statistically significant. Citizens of different nationalities differed in their willingness to let a computer analyse their expenditure. Turkey and Romania feature a higher level of acceptance than Poland of robo-advice for expenditure analysis. The inhabitants of Austria and Germany expressed the most reluctance to have a computer program give financial advice. H1 was confirmed.

The results of correlation analyses showed that in most countries age was associated with less acceptance for a computer program to make investment decisions. The strongest relationship in this regard was in the case of the United Kingdom, followed by the USA and Australia. Also in most countries, the willingness for a computer program to make investment decisions was proportional to the number of people in the household, with the United Kingdom featuring the strongest relationship in this regard. For all analysed countries, correlation analyses showed that age is inversely proportional to the acceptance of a computer for analysing expenses and recommending improvements. The strongest relationships in this regard were also demonstrated in the United Kingdom, followed by the USA and Australia, with Turkey having the weakest correlation. Furthermore, in most countries, the higher the number of people in the household, the greater the willingness for a computer program to analyse spending habits and recommend improvements. This relationship was also the strongest in the case of the United Kingdom and the USA. H2 was found to be true.

Also in most countries, more people in the household translated into a greater willingness for a computer program to make investment decisions, with the United Kingdom featuring the strongest correlation in this regard. Additionally, in most countries the number of people in the household was proportional to the willingness for a computer program to analyse spending habits and recommend improvements. This relationship was also found to be the strongest in the case of the United Kingdom and the USA. H2 and H3 were confirmed.

The results of correlation analyses indicated that in most countries age was associated with less acceptance for a computer program to make investment decisions. The strongest relationship in this regard was found in the United Kingdom, followed by the USA and Australia. For all analysed countries, correlation analyses showed that as age increased, acceptance for a computer to analyse expenses and recommend improvements fell. The strongest correlations in this respect were also demonstrated for the United Kingdom, followed by Australia, with Turkey having the weakest. H4 was confirmed to be accurate.

The results of the Mann-Whitney U tests proved to be significant, which means the countries analysed featured differences between men and women in terms of their acceptance of robo-advice for investment. Such gender differences were not demonstrated in the case of Poland, the Czech Republic, Romania, Spain and Turkey. In all the remaining countries, men were more willing than women for a computer to make investment decisions on their behalf, with Germany and Austria having the largest gender divide. The results of the Mann-Whitney U tests were mostly irrelevant, which means that there were no differences between men and women in the analysed countries in terms of their acceptance of robo-advice for analysing expenses and recommending improvements. Such differences were only shown to apply to Germany, the Netherlands and Turkey. In the case of Germany and the Netherlands, men were more likely to have a computer analyse their expenses, while in the case of Turkey, women were more likely to do so. H5 was confirmed to be accurate.

The results of the Mann-Whitney U tests proved to be significant for the most part, meaning that the countries analysed featured differences between working and non-working people in terms of their acceptance of robo-advice for investment. Such differences were not found in the case of Poland, Austria, the Czech Republic, Luxembourg and Romania. In the remaining countries, it was demonstrated that working people were more favourably inclined towards robo-advice for investment while the largest differences were found in the United Kingdom. The results of the Mann-Whitney U tests in terms of robo-advice acceptance in the field of expenditure analysis again proved to be significant, which means that in the countries analysed there were differences between working and non-working people. Such differences were not revealed in the case of Poland, Austria, the Czech Republic and Romania. In the remaining countries, working people would be more likely to use robo-advice to

analyse spending and recommend improvement than non-working people. The greatest differences were also found in the United Kingdom. H6 was confirmed.

The research issues presented here are new, and the research results have practical significance and application value for entities offering automatic financial advice and household budget monitoring.

INVESTMENT CLIMATE AND ITS INFLUENCE ON THE DEVELOPMENT OF ENTREPRENEURSHIP: PRACTICE OF THE REPUBLIC OF KAZAKHSTAN

Arslan Kulanov [1], Saltanat Tamenova [2], Kamilya Amenova [3], Alma Karshalova [4], Leila Tussupova [5]

[1,2,5] *Turan University, Satpaeva Street, 16a, Almaty, 050000, Kazakhstan*
[3,4] *Narxoz University, Zhandosova Street, 55, Almaty, 050035, Kazakhstan*

Abstract. The purpose of this study is to identify problems that impede the investment activities of small and medium-sized enterprises (SMEs) in the Republic of Kazakhstan, as well as to study the recommendations of the leading representatives in the business community regarding the activities of the authorities in creating a favorable investment climate. Expert interviews with the Kazakhstan's entrepreneurs, representatives of Akimats, and representatives of the scientific community have been conducted during the study. The results of the expert survey allow to conclude that the Republic of Kazakhstan has developed a rather favorable investment climate in general, and the authorities have done significant work to create conditions for business development. However, according to the expert review, some problems in the implementation of investment projects by SMEs still remain. According to the experts, the most significant problems include the underdeveloped transport and logistics infrastructure, the lack of available production and office space, and difficulties with registering land, attracting foreign labor, as well as obtaining various permits required for doing business. As a result of the study, the recommendations have been made for eliminating the barriers that hinder the creation of a favorable investment climate and the successful development of SMEs in the Republic of Kazakhstan. According to the experts, the attention should be focused on creating and developing ready-made platforms for doing business for investors, improving transport and logistics infrastructure, speeding up the state property privatization, etc.

Keywords: investment climate; business environment; entrepreneurship; business climate; investment activities

1. Introduction

Integration with global markets and the increasing competitiveness of the private sector have contributed to the unprecedented growth of many economies – especially those of Asian countries, such as China, Vietnam, etc. (World bank, n.d.; Siddique et al., 2020; Adeniran et al., 2020).

The development of entrepreneurship in the Republic of Kazakhstan is the most important factor in influencing the welfare of the country's economy (Serikbaeva, Bektanov, Bekturganova, 2019). More than 1.2 mln SMEs operated in the country and over 3.3 mln people were employed in the sector at the beginning of 2019 (Statistics Committee of the Ministry of National Economy of the Republic of Kazakhstan, n.d.).

At the same time, the economic potential of SMEs in the Republic of Kazakhstan is not fully utilized. The number of people currently employed in SMEs in the Republic of Kazakhstan is 21.6 %. In most advanced economies, this indicator is in the range of 45 – 75 %. For example, the number of people employed in SMEs is 44.9 % of the total employment in Germany, 50 % - in France, 56.1 % - in the UK, 73.3 % - in Italy, and 72.9 % - in Korea (OECD.stat, n.d.).

The SMEs' contribution of the value added to the GDP in the Republic of Kazakhstan is 28.4 % (Statistics Committee of the Ministry of National Economy of the Republic of Kazakhstan, n.d.). For comparison, this indicator is 76.6 % in Korea, 63.4 % - in Italy, 45.6% - in the UK, and 43.4 % - in France (OECD.stat, n.d.).

Foreign direct investment (FDI) is one of the main catalysts for the development and encouragement of the economic activities of SMEs. It is generally recognized that the importance of FDI for the country's economic prospects is growing amid the increasingly globalized business environment. Attracting investment in economic development is especially important for the Republic of Kazakhstan, which has positive prospects for the growth of consumer markets and unrealized natural resource potential.

For the Kazakhstan's SMEs, the potential benefits of attracting investments are related to expanding market opportunities and internationalizing their business, improving managerial skills, using new technologies, and facilitating access to capital (Dyussembekova et al., 2019).

The Republic of Kazakhstan observes the positive dynamics in the development of investments: the inflow of FDI in the country's economy increased by almost 58 % over four years, from 15.4 bln USD in 2014 to 24.3 bln USD in 2018 (Statistics of direct investment by the direction of investments, n.d.).

A favorable investment climate is one of the main reasons for the observed growth in investment activities in the Republic of Kazakhstan. While huge reserves of Kazakhstan's hydrocarbons and mineral resources remain the basis of the economy, the government of the Republic of Kazakhstan creates the proper conditions: the investment law is enforced, the relevant regulations are adopted, preferences for certain types of production are put in effect, the money is raised to invest in free economic zones (FEZs), and an appropriate program of industrial and innovation-driven growth is adopted.

Kazakhstan adopted the OECD Declaration and Decisions on International Investment and Multinational Enterprises and became an associate member of the OECD Investment Committee in June 2017 (Madiyev et al., 2018).

In August, 2017 the government of Kazakhstan adopted a new National Investment Strategy for 2018 – 2022, developed together with the World Bank, which outlined new coordination measures to improve the investment climate, privatization plans, and a policy of economic diversification. The strategy aims to increase the total FDI inflow by 25 % by 2022 (Decree of the Government of the Republic of Kazakhstan No. 498, 2017).

The efforts of Kazakhstan to remove bureaucratic barriers, in particular through a "single-window" program for investors, were moderately successful, and Kazakhstan ranked 28th out of 190 in the World Bank's ranking on the ease of doing business in 2019 (World Bank, 2020).

Despite ongoing institutional and legal reforms, such problems as corruption, bureaucracy, and limited access to skilled labor remain relevant in some regions of Kazakhstan.

2. Literature review

Many scientific works are devoted to the problems of the SMEs development. Many authors agree that entrepreneurship is a powerful economic force that creates the majority of new jobs and contributes to economic growth, which determines the interest of the state in this phenomenon (Burov, 2013; Dethier, Hirn, Straub, 2011; Aterido, Hallward-Driemeier, Pages, 2007; Dollar, Hallward-Driemeier, Mengistae, 2005; Merzlova, Sharkova, 2013; Rubio-Mozos, García-Muiña, Fuentes-Moraleda, 2019; Kowo, Adenuga, Sabitu, 2019).

The steady growth of SMEs reflects the stability of the economy (Rubio-Mozos, García-Muiña, Fuentes-Moraleda, 2019). Although the concept of entrepreneurship has not been yet completely formed, the interest of researchers in it is growing (Wiklund et al., 2011).

Researchers note that creating a favorable environment for the dynamic development of the entrepreneurship sector is directly dependent on government policies aimed at creating a transparent, stable, and predictable investment climate (Dethier, Hirn, Straub, 2011; Novolodskaya et al., 2019; Savitz, Dan Gavriletea, 2019).

The investment climate is the economic, financial, and sociopolitical conditions in the country that influence the willingness of individuals, banks, and institutions to issue loans and to acquire shares (to invest) in the enterprises operating in that country (Ongbwa, 2017).

The investment climate in a given country or region can be defined by a wide range of factors that determine whether domestic and foreign investments occur: the soundness of macroeconomic policies, the strength of economic and political institutions, the regulatory framework, the quality of infrastructure and other services, etc. (Vijayalakshmi et al., 2019).

As a rule, factors contributing to the development of the investment climate are selected during surveys of company managers and owners, as well as during interviewing potential investors.

Much of the research literature is devoted to the study of the relationship between the characteristics of the business regulatory environment and enterprise performance, as well as macroeconomic results (Rose, Mamabolo, 2019; Lynch-Wood, Williamson, 2014; Asim et al., 2019; Avan, Kraslawski, Huiskonen, 2017). However, the studies in general do not give final results regarding the direction of causal relationships. A hypothesis is usually made that better regulation encourages better economic outcomes (Graafland, Bovenberg, 2019).

Many aspects influence the quality of the country's investment climate and overall competitiveness. A number of global benchmarking initiatives have been developed by now, which can be useful in understanding the investment climate of business in countries (Borkova et al., 2019).

Most of these initiatives are built around five topics (Golaido, Soboleva, 2015): 1) competitiveness and investment climate; 2) prospective restrictions on the part of enterprises; 3) business and investment barriers; 4) risk and uncertainty of the policy; and 5) the cost of operations.

With regard to competitiveness and investment climate, the data on prospective restrictions on entrepreneurship are provided in the World Bank Group's enterprise surveys. The World Bank Group's Doing Business indicators measure regulatory concerns for enterprises based on a combination of statistics, regulatory information, and enterprise surveys (World Bank, 2020). These surveys and indicators are complementary, but have different approaches to benchmarking of the business environment quality in different countries.

The World Economic Forum's Global Competitiveness Index (World Economic Forum, 2019) is another source of information, which combines the results of opinion polls of managers and quantitative data in an attempt to measure the economy competitiveness based on a set of elements covering broad socioeconomic aspects, such as institutions, infrastructure, macroeconomic stability, financial system, dynamism of entrepreneurial activities, innovative potential, etc.

The United Nations Industrial Development Organization (UNIDO, 2018) evaluates more than 100 countries in terms of their industrial competitiveness and their production and export potential, in particular.

The policies of the Organization for Economic Cooperation and Development (OECD) address a range of areas that influence investment. The OECD uses such indicators as the volume of external flows and inflow of FDI, external and internal positions of FDI, as well as income from the export and inflow of FDI in order to assess the investment climate. The index of regulatory restrictions on FDI is one of the most important indicators that determine the factor of the country's attractiveness for foreign investment (Kalinova, Palerm, Thomsen, 2010).

As such, a rather extensive methodological base for assessing the state of the investment climate is presented in the scientific literature at the moment. However, the leading global indicators of various aspects of the investment climate are not sufficient to get a complete picture of the problems of investment competitiveness of small and medium enterprises in countries with developing economies.

The hypothesis of the study is the assumption that a favorable investment climate helps raise capital and increase the competitiveness of SMEs.

3. Methods

The main method of research was a representative sociological survey of experts. The experts were selected according to a preplanned list sample. Three hundred and eleven people were invited as experts from among the heads and deputy heads of SMEs in the Republic of Kazakhstan, 32 representatives of Akimats with the economic profile, and 27 representatives of the scientific community competent in the subject of the study. If an expert did not want or could not participate in the interview, then other people competent in the subject of the study, i.e., their deputies, assistants, and colleagues, were allowed to participate in the survey.

The main objectives of the survey were to obtain data describing the state of the investment climate, including problems and prospects for the development of SMEs, and to prepare recommendations for improving the investment climate in the Republic of Kazakhstan.

The survey was conducted using the approved questionnaire with formalized questions. A personal interview with an expert was used as the interview method. If a personal interview with the expert was impossible, the survey was carried out by phone or by email. The interview was recorded using a voice recorder (after that, the audio was transcribed into Word).

Based on the results of the survey, a general list of factors that have both positive and negative impact on the investment climate of the country has been compiled. By the nature of the impact on the innovation climate, all factors are divided into several groups:

• Factors of the country's natural resource potential - mineral reserves, availability of own fuel and energy resources, level of environmental pollution;

• Factors of the institutional environment and socio-political stability - the level of the regulatory framework for the protection of property rights and regulation of small and medium-sized businesses, the development of competition mechanisms and market institutions, the tax environment, government support measures for small and medium-sized enterprises, measures to ensure the execution of contracts;

• Infrastructural factors - the quality of financial infrastructure, transport accessibility, the state of energy infrastructure, the level of ICT development, the provision of housing for the population;

• Factors of economic development - macroeconomic stability of the country, GDP per capita, inflation, openness of the economy to international trade, annual growth in value added of industrial sectors, gross capital formation, final consumption expenditures.

• Labor market development factors - unemployment rate, labor productivity in industry, agriculture, services sector.

The distribution of the survey participants by the beginning of their activities was uniform: 18 % carried out their activities for no more than three years, every fifth entrepreneur began to carry out their activities no earlier than one year ago – 22 %, or six months ago – 22 %. Only 18 % of the entrepreneurs had been working for more than three years.

4. Results

The results of the survey reveal that most experts positively assess the measures of the authorities of the Republic of Kazakhstan aimed at the development of SMEs. For more convenient presentation, the experts' responses were divided into three groups: high ratings (positive), average ratings (neutral), and low ratings (negative).

Translating into a five-point rating scale, most entrepreneurs usually give these measures four points. At the same time, all representatives of government bodies that took part in the survey rated the existing support measures as high (Figure 1).
Fig. 1. Assessment of the measures of local authorities aimed at the development of entrepreneurship, % of the respondents
Source: Compiled by Authors

At the same time, it can be noted that there is a high proportion of the experts in the overall distribution who assess the measures of government bodies aimed at developing SMEs in the Republic of Kazakhstan at an average level, noting that the shortcomings are still present (28.1 % of the respondents), and who rate these measures as low (7.6 %). In addition, 18 experts from among entrepreneurs indicated that they found it difficult to assess these measures because they had never noticed or encountered them. The respondents consider these measures to be insufficient because the authorities do not always want to "hear" entrepreneurs and are not always open.

The experts assess the measures aimed at creating a favorable investment climate in the Republic of Kazakhstan as lower than the measures to develop entrepreneurship in the country.

The share of the experts who took part in the survey and found it difficult to assess these measures, since they had never encountered or heard anything about them, was almost 15 % (Figure 2).

Fig. 2. Assessment of the measures aimed at creating a favorable investment climate in the Republic of Kazakhstan
Source: Compiled by Authors

At the same time, 31.1 % of the business, government, and the scientific community representatives in the Republic of Kazakhstan highly rate the measures aimed at creating an investment climate.

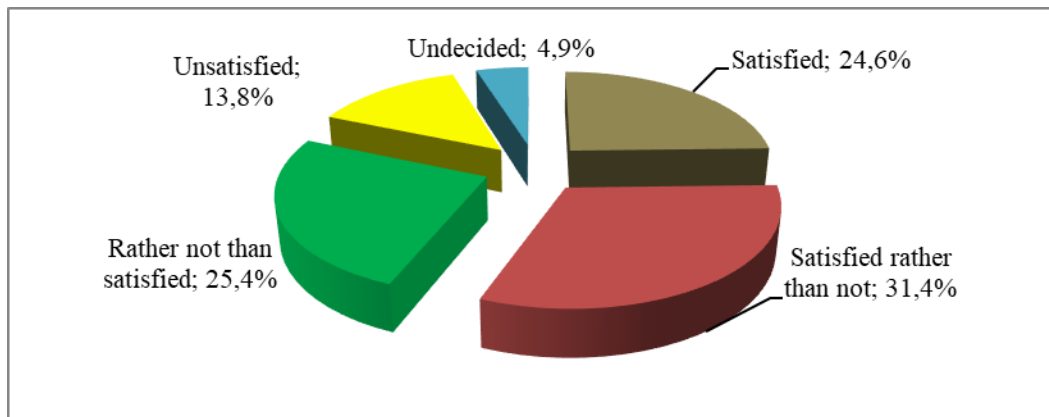
At the same time, the shares of the experts who rated the measures to create an investment climate in Kazakhstan at an average and low level were approximately equal. For example, 27.6 % of the experts highly appreciate the measures aimed at creating an investment climate. At the same time, 26.5 % of the experts, on the contrary, rate these measures very low. Most experts (84.3 %) believe that Kazakhstan is already an attractive and promising field for raising investment. The level of satisfaction with the business conditions existing today in the Republic of Kazakhstan among the experts is rather at the average level (Figure 3).


Fig. 3. The level of satisfaction of SMEs' representatives with the business environment in Kazakhstan
Source: Compiled by Authors

427

The survey results indicated that entrepreneurs were generally not critical in assessing the conditions for doing business, but they did not provide high ratings either, noting that there were still some problems in this area. At the same time, almost 5 % of the business representatives found it difficult to answer this question.

The experts note that despite the fact that much work has been done in the Republic of Kazakhstan in terms of the measures aimed at developing SMEs in general, there are big problems with the implementation of investment projects of SMEs. According to the experts, the largest share of serious problems in the implementation of investment projects is noted in infrastructure and logistics (51.1 %) and the lack of available production and office space (48.9 %) (Figure 4).
Fig. 4. Problems of SMEs that arise when implementing investment projects
Source: Compiled by Authors

In the course of the survey, the experts were invited to identify factors that encouraged the investment activities of SMEs. The experts noted the availability of significant reserves of fossil fuels and other minerals and metals, the laws in force in the Republic of Kazakhstan on the protection of property rights, a fairly favorable tax environment, and a range of government support measures for SMEs as the main encouraging factors that influenced the investment climate (Figure 5).
Fig. 5. Factors that encourage the investment climate development
Source: Compiled by Authors

More than 40 % of the respondents named the development of competition mechanisms and market institutions, macroeconomic stability, established rules for enforcing contracts, legislation on the SMEs regulation, and the quality of infrastructure as the main encouraging factors.

In general, the experts believe that these factors should ensure and encourage the development of SMEs and the stability of the investment climate. It must be noted that the experts who took part in the survey mentioned that the factors influencing the state of the investment climate and the development of SMEs were interconnected and usually did not differ.

5. Discussion

In conclusion, the experts were asked to give their recommendations for the creation of a favorable investment climate and the successful development of SMEs in the Republic of Kazakhstan.

The most popular recommendations on the creation of a favorable investment climate and the successful development of SMEs in the Republic of Kazakhstan mentioned by the experts include the creation and development of ready-made platforms for doing business for investors, improvement of infrastructure, speeding up the privatization process, etc. (Figure 6).
Fig. 6. Recommendations on the creation of a favorable investment climate and the successful development of SMEs
Source: Compiled by Authors

Almost two-thirds of the experts (65.9 %) believe that providing investors with ready-made platforms for doing business is an effective tool to attract investments in the country's economy. Such platforms include special economic and industrial zones (SEZ and IZ) and investment contracts.

It must be noted that 12 SEZs have already been created and are operating in the Republic of Kazakhstan. They have already proved their effectiveness. According to the Ministry of Industry and Infrastructure Development of the Republic of Kazakhstan, the budgetary costs for the construction of the infrastructure of all SEZs amounted to 314.3 bln tenge, while the volume of the raised investment amounted to approximately 910 bln tenge. This means that one tenge from the budget invested in the SEZ infrastructure allowed to raise 2.8 tenge of private

investments. At the same time, 85.9 bln tenge were invested in the IZ infrastructure. As such, 2.1 tenge of investments were attracted per each tenge invested from the budget. In total, 183 projects were launched in the territories of SEZs, of which 46 projects were with foreign participation, 15.5 thousand jobs were created, and about 150 bln tenge were repaid to the budget as taxes.

At the same time, 38.9 % of the experts noted that the SEZs in the Republic of Kazakhstan were not working efficiently enough, despite the significant level of budget investments in the development of zonal facilities. This requires timely diagnosis of the factors that impede the success of SEZs and targeted actions to address them.
The experts name the following main reasons for the low efficiency of some SEZs: weak management structures or too many institutions involved in the management of SEZs, poor location of facilities requiring large capital costs or situated far from the infrastructure centers; poor design of areas with inappropriate equipment or maintenance, etc. (Figure 7).

Fig. 7. Key problems for SEZs (% of the respondents)
Source: Compiled by Authors

Regular monitoring and evaluation mechanisms should become a key aspect of the institutional and managerial structure of the SEZ. There is no systematic evaluation of the performance of the zones in the Republic of Kazakhstan today, and no mechanisms have been created to solve the problems of insufficient performance of SEZs.

It seems appropriate to draw attention to international practice in the formation of a system for monitoring the performance of SEZs. For example, China regularly evaluates the performance of high-tech development zones (HTDZs), as well as economic and technological development zones (ETDZs). The 1996 Administrative Decree of the Ministry of Science and Technology requires regular evaluation of HTDZs. The 2013 rating index system includes four categories and 40 indicators, such as:

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810

- Knowledge creation and technological innovation: the level of employees' education, R&D expenses, the number of research institutes and incubators, etc.

- Capabilities for industrial modernization and structural optimization: the number of high-tech enterprises, ratio of enterprises in the service sector, registration of intellectual property, the number of registered companies, etc.

- Internationalization and participation in global competition: the ratio of employees who have graduated abroad, the ratio of foreign personnel, the number of foreign branches, registration of intellectual property abroad, etc.

- Sustainable development potential: the ratio of employees with Master's and Doctor's degrees, growth rate of the number of companies or tax revenues, volume of new investments, energy consumption, etc.
Evaluation of the innovative potential of HTDZs has been used as an additional performance criterion since 2016.

The Ministry of Commerce of China has been conducting an annual ETDZ assessment since 2016. The exit system applies to the lowest rated ETDZs for two consecutive years. Evaluation of ETDZs is based on five criteria, namely industrial potential, technological innovation, regional integration, environmental protection, and administrative efficiency. The Ministry of Commerce publishes a list of top 30 zones and the names of top 10 zones in the categories of industrial potential, innovation, FDI, and foreign trade, respectively.

The Russian Federation has developed a comprehensive method for monitoring and evaluating the performance of its SEZs in a similar manner (Nikitina et al., 2018; Levkina, Sakharova, Edelev, 2020). The government monitors and evaluates several SEZ types in the Russian Federation: industrial production, technological innovation, tourism and recreation, and ports. The legislation of the Russian Federation establishes six indicators of the SEZ performance: investment attractiveness, business environment, infrastructural support, access to land resources, investment activity of the SEZ residents, and information transparency of the SEZ website. The evaluation is carried out annually, and zones are ranked according to certain criteria. This process mainly served to create equal pressure on the ineffective zones and regional authorities of the area in which they operate. Unscrupulous performers are excluded from the SEZ list and shut down.

In addition to the SEZs, the creation of SME parks is also a promising tool for creating a favorable investment climate in the Republic of Kazakhstan.

The SME parks are autonomous geographical areas with high-quality infrastructure facilities that host industrial enterprises. The main goal of the SME parks is to create SMEs that produce high value-added products but lack the necessary funds to invest in the development of their own basic infrastructure facilities, though they are able to pay for the services provided to them.

The government secures infrastructure facilities and, therefore, creates favorable conditions for attracting SMEs. The general goals of the SME parks are to take advantage of local and international investment opportunities by creating processing parks in strategic areas rich in raw materials.

In the course of the survey, the experts identified a number of priority areas for the development of the SME parks and industrial zones in the Republic of Kazakhstan: reimbursement of investor costs for building and assembly works on infrastructure construction (47.8 %), infrastructure construction by providing a preferential rate (30.3 %), and optimization and automation of land allocation (27.3 %).

More than half of the surveyed experts (52.2 %) highlighted the availability of high-quality infrastructure as a recommendation on creating a favorable investment climate and successful development of SMEs in the Republic of Kazakhstan. Almost all regions of Kazakhstan need additional investments in the logistics infrastructure. According to the ESCAP, the annual need for investments in the infrastructure of the Republic of Kazakhstan is 2.1 % of the GDP, of which 0.7 % of the GDP is for the transport infrastructure, 0.9 % is for the energy infrastructure, 0.3 % is for the water supply and sanitation infrastructure, and 0.2 % is for the ICT (Branchoux, Fang, Tateno, 2017). Improving infrastructure is especially important in the regions in order to attract foreign investors and FDI.

More than half of the experts (51.4 %) believe that the privatization process should be sped up in order to create a favorable investment climate. A large share of state participation strengthens monopolistic trends and limits the development and growth of enterprises and their market orientation.

The privatization process should be sped up to make the development of enterprises more efficient. To speed up the privatization process, an inventory of state property and assets should be compiled, and their market value should be determined with the involvement of an independent appraiser. One of the prerequisites for the privatization process is its transparency and openness. State property may be sold through an open electronic auction rather than through direct sales.

In addition to those mentioned above, the expert recommendations include the need to simplify procedures related to the attraction and hiring of foreign labor, promoting the country's investment image abroad, raising SMEs awareness of the existing measures of state support, removing barriers to the participation of SMEs in public procurement, etc.

Therefore, it is recommended for authorities and competent authorities to pay an increased attention to the measures proposed by the experts and consider the possibility of their implementation in the future.

Conclusions

The results obtained in the course of the study confirm the hypothesis that a favorable investment climate helps raise investment in the development of the country's economy and increase the investment activities of SMEs of the Republic of Kazakhstan.

According to the experts, the main problematic issues that arise during the investment activities of SMEs include the underdeveloped transport and logistics infrastructure, the lack of available production and office space, as well as difficulties with registering land.

In general, the experts have identified the following factors encouraging the investment activities of SMEs: availability of significant reserves of fossil fuels and other minerals and metals, the current legislation in the Republic of Kazakhstan on the protection of property rights, a rather favorable tax environment, and a range of the state support measures for SMEs.

The Kazakhstan's experts have made suggestions to improve the investment climate in the course of the survey. The most numerous expert recommendations relate to the creation and development of ready-made platforms for doing business for investors, improving transport and logistics infrastructure, and speeding up the privatization of state property.

Abstract. The cultural crisis and the sense of loss of contemporary man are in a way a consequence of the imbalance between the uneven development of the sphere concerning his mentality and the technical and technological progress in the workplace. An increasingly important element of the contemporary human working environment is the culture of security, and one of its important parts is the organisational culture. This culture manifests itself in the behaviours and relations of individuals and employee teams, in courts and attitudes, in the way of solving problems and conflicts, organising work and human cooperation. It is an inseparable element of interpersonal relations and shaping order between cooperating people. The subject of the research was the organisational culture of TECHZBYT trade company. However, the aim is to determine to what extent the organisational culture of TECHZBYT company influences the level of employee security culture. Based on the subject and aim of the research, the following main research problem was formulated: What is the impact and significance of TECHZBYT's organisational culture on the effectiveness of operation and on the level of employee security culture? The research area has been made the TECHZBYT company, which is a local trading company with a certified quality management system in accordance with the requirements of the ISO 9002 standard. It is a leading trading and service company located in the Pomeranian Province, which deals with trade in metallurgical and construction products. The mission of TECHZBYT Sp. z o.o. is to meet customer expectations by distributing construction products of excellent quality in convenient places. The surveyed group consisted of employees of Techzbytsp. z o.o. and the research method used was a diagnostic survey (questionnaire tool). The group consisted of 30 basic level employees. The article consists of several parts, in the first part there is an introduction to the issue. Next, selected examples of defining security culture are presented. In the next part, the author's team indicated the need to conduct research in the area of a given organisation. The final part is empirical research on the evaluation of security culture in the organisational behaviour of employees.

Keywords: organisational culture; security; organisation; security culture

1. Introduction

The cultural crisis and the sense of loss of contemporary man are, in a way, a consequence of the imbalance between the uneven development of the sphere concerning his mentality and the technical and technological progress around it. Culture is an increasingly important element of the contemporary human security environment.

Therefore, the culture, and especially the culture of security, will be positively shaped by the broadly understood self-defence skills, supporting the strengthening of the sense of human security. We deal with it in all social strata and age ranges. Its knowledge, but above all the way it is manifested, influences the way we perceive and think about security. An important element of the culture of security is the subject's behaviours and actions, including his or her citizen's cooperation. All these elements become significantly more important in difficult or crisis situations, during which the culture of security is particularly visible.

A security culture is characteristic of all human activities in an organisation, including management, and affects all significant aspects of its functioning and the basic instruments and structure, strategy and procedure. Each organisation has its own specific characteristics, which influence what happens inside it and its contacts with the environment, often stronger than the authority of the leaders or the formal structure.

A culture of security is manifested in the behaviour and relations of individuals and employee teams, in courts and attitudes, in the way problems and conflicts are solved, work organisation and human interaction. It is an inseparable element of interpersonal relations and shaping order between cooperating people. The security culture in an organisation permeates all areas of activity of each institution, constituting a bridge between its past and future. Culture integrates, unifies, stabilizes, reduces uncertainty, promotes common vision of goals and facilitates finding ways to solve problems. It provides a strong foundation for the strategic activities of an organisation (J. Penc, 2010).

Security culture has quite a big connection with the broadly understood organisation culture. The starting point, and at the same time the main reason for its research was the need for information from management. The necessary information will enable or facilitate making a specific decision or a combination of decisions concerning the organisational improvement of the company, but also raise the security culture among employees to a higher level. Therefore, it is worthwhile to first of all examine the shape and profile of the organisational culture, identify the factors determining its change, determine its impact on the company's effectiveness, and assess the level of security culture.

The subject of the research was the organisational culture of TECHZBYT trade company. However, the aim is to determine to what extent the organisational culture of TECHZBYT company influences its task effectiveness on the one hand and on the other hand the level of employee security. On the basis of the subject and aim of the research, the following main research problem was formulated: *What is the impact of TECHZBYT's organisational culture on the effectiveness of its functioning and on the level of employee security culture*?

The following specific problems were formulated:
1) How is organisational culture understood and perceived by the subjects and what are its main determinants?
2) Which elements of the company's activities are most influenced by the organisational culture?

3) What is the relationship between the company's organisational culture and the security culture of employees?

The research area has been made the TECHZBYT company, which is a local trading company with a quality management system certificate in accordance with the requirements of the ISO 9002 standard. It is a leading trade and service company located in the Pomeranian Province, which deals with trade in metallurgical and construction products. The mission of TECHZBYT Sp. z o.o. is to meet customer expectations by distributing construction products of excellent quality to for their customers' convenient places.

The group studied consisted of employees of Techzbyt sp. z o.o. The research method used was a diagnostic survey and a survey questionnaire. The surveyed persons were divided into two groups. The first group consisted of the managerial staff in the number of 10 people, the second group consisted of the basic level employees in the number of 30 people.

2. Selected examples of defining a security culture

Culture is characteristic of all human activities within an organisation, including management, and affects all significant aspects of its functioning, including its basic instruments and structure, strategy and procedure. Each organisation has its own specific property, which influences what happens inside it and its contacts with the environment, often stronger than the authority of leaders or formal structure. Culture manifests itself in the behaviour and relations of individuals and employee teams, in courts and attitudes, in the way problems and conflicts are solved, in the organisation of work and human interaction. It is an inseparable element of interpersonal relations and shaping order between cooperating people. Culture permeates all areas of activity of each institution, being a bridge between its past and future. Culture integrates, unifies, stabilizes, reduces uncertainty, promotes a common vision of goals and facilitates finding ways to solve problems. It provides a strong foundation for the strategic activities of an organisation (Penc, 2010).

A review of various cultural concepts by A.L. Kroeber and C. Kluckhohn gave rise to a comprehensive, multi-faceted definition by them: "Culture consists of overt and covert patterns, of behaviours learned and transmitted by symbols, forming the specific heritage of human groups, and of the products of these behaviours: the core of culture are traditional, i.e. grown and selected in a historical process, ideas, and the values attached to them; cultural systems can be considered either as products of human activity or as conditions for further human activity" (Kroeber, & Kluckhohn, 1952).

This definition, very broadly speaking, is a kind of a boundary - on the one hand closing the historical aspect of the term's development, and on the other hand it contains a very rich collection of contemporary humanities, in the circle of research of which there is also culture, often giving the basis for formulating contemporary definitions of the term.

It is also worth mentioning here the rather commonly used form of classification of cultural fields, dividing it into material and spiritual. Very often the boundary between material and spiritual culture coincides with the distinction between culture and civilisation. The distinction between material and spiritual culture is often speculative. Nevertheless, these divisions seem important (culture - civilisation, spiritual culture - material culture), as the whole will constitute culture in a broad sense.

The culture of security through its elements allows to create a certain key to the interpretation of events, to direct actions aimed at strengthening the sense of human security. The use of its potential enables the creation of a stable environment conducive to security in its broadest sense.

The term security culture was first used by the Atomic Energy Agency, which issued a report on the Chernobyl disaster. Security culture is treated as a component of the organisational and social culture and as a whole of collective actions consisting of the application of organisational and interorganisational practices aimed at the protection of the individual employee and the entire working environment (Gherardi, Niccolini, 2000). The culture is also a set of values and beliefs within the organisation, creating specific patterns of behaviour. It is the result of individual and collective values, characteristics, perceptions, competences and patterns of behaviour that determine commitment to health and security at work.

The very concept of security culture, according to Professor M. Cieślarczyk is "a model of basic assumptions, values, norms, rules, symbols and beliefs characteristic for a given subject, influencing the way it perceives challenges, opportunities and/or threats in its closer and further environment, as well as the way it feels and thinks about security (...), and the related way of behaviour and action (cooperation), in various ways "learned" and articulated by this subject, in the processes of education in its broadest sense, including natural processes of internal integration and external adaptation and other organisational processes (...), as well as in the process of strengthening the defence in its broadest sense (not only militarily) (...), serving the harmonious development of this entity and its achievement of security in its broadest sense, for the benefit of itself and its environment" (Cieślarczyk, 2009).

And A. Filipek writes: "the culture of security can be treated as specific tendencies of individual communities or social groups, conditioned by an accepted hierarchy of values, serving to build a broadly understood defence, the result of which will be the actual ability to prevent threats, as well as the ability to create one's own development, conducive to the preservation and renewal of identity" (Filipek, 2008). Despite some differences in the interpretation of the term "security culture", it can be seen that both definitions attach great importance to the issue of values. This means that shaping the broadly understood security of students, based on an internal hierarchy of values, will be a manifestation of an important aspect of their security culture.

One of the most popular definitions of occupational security culture developed by the UK *Health and Safety Executive* (HSE) indicates that an occupational security culture is the result of individual and group values, attitudes, perceptions of competence, behavioural patterns and the style and quality of security management in an organisation. Organisations with a positive security culture are characterised by communication based on mutual trust, a common perception of the importance of security and confidence in the effectiveness of preventive measures (Horbury, Bottomley, 1997).

Shaping an appropriate security culture is one of the important elements of occupational health and safety/security management (Polish Standard PN-N-18001, 1999). Shaping a security culture is a continuous and multidimensional process to which all groups of employees in the company must submit. It is as much about passing on the relevant theoretical knowledge as it is about introducing it into everyday use. A safe work culture is created and then reproduced according to the system of accepted meanings in a given group of employees. Employees will only be willing to repeat their behaviour according to the adopted pattern if the adopted pattern is an understandable, obvious and unquestionable way of behaviour for them.

M. Cieślarczyk calls the dimensions of security culture "pillars of security culture" (Cieślarczyk, 2010). The components of these dimensions intertwine to some extent. For example, knowledge, which is a component of the first dimension of the culture of security, in addition to the values and principles that are recognised by man, is also the domain of the second rational-organisational-legal dimension of the culture of security (also connected with technical thought).

While recognizing the types, characteristics and dimensions of a security culture, one should not forget about its very close relationship to security
For both security and culture, there are two simultaneous characteristics - space and time. Physical space gives room for the emergence of security regions or threat areas and allows culture to expand to cover more and more territory.

Time creates a system of reference in which the process of building a culture takes place in a certain territory, twinned with the process of development of human individuals, social groups and entire nations - this development determines the level of their security.

The development process is the most powerful prevention mechanism, counteracting all threats and, even according to the definition of security - can be considered as an analogy of a security phenomenon in the process.

Culture is not only a certain "added value", but also represents an autonomous potential for the defence of the actors - in the military, political, socio-cultural, economic, environmental, health, and in such spheres of activity as legal-organisational, technogenic or cybernetic.

Culture in relation to entities operating in the area of its impact, from the personal scale to the social scale, is a mechanism that can influence the attitudes and behaviour of these entities in specific situations, processes or events that bring with them various challenges, opportunities, risks and threats (Piwowarski, 2016).

In our view, the culture of security is the awareness of shaping life in the perspective of the broadly understood balance between the structural thesis and deconstructive antithesis, is a subjective sense and, at the same time, a holistic way of thinking, a form of subjective activity in shaping the most perfect forms of existence, inscribed in sustainable development directions. In terms of safety culture, it is worth emphasizing the role of the subject's autonomy as a conscious person, perceiving and assessing processes and phenomena occurring in the environment and adequate to the needs of its change (Gierszewski et al. 2020).

Subjectivity embedded in the space of security is a reflection of the ontological, epistemological and ethical paradigm, and the culture of security is the pursuit of the development and improvement of such forms of duration that best meet the needs and ideas of the subject. The very expression "security culture" implies a humanistic provenance of security and stains its subjective dimension. Therefore, it is worth asking a question about the place and role of shaping a safety culture in an organisation.

The term 'security culture' refers to society, a group of people or organisations, and to individuals. That is why the culture of public, enterprise and individual security can be distinguished. The security culture of an enterprise is an important for employees' state of awareness of threats, standards of conduct in an emergency and organisational processes that affect the taking into account of safety in the company, organising tasks, supervising and assessing employees and explaining the causes of accidents. Security culture can also serve as a very useful theoretical model, having an explosive power, useful among others in the discipline of security sciences. Security

culture is quite an important determinant of the broadly understood organisation culture. The origins of the concept of "organisation culture" can be seen in the development of two currents in organisation and management theory. The first stream originates from the company's environment and stems from questions about the influence of the national culture of a particular community on management. The second is the so-called behavioural school, where interpersonal processes and group dynamics within an organisation are of interest (C. Douglas, 2017). In economic literature, depending on the concept and approach, the definitions of organisational culture take very different shapes. Some researchers represent the view that culture is not something that an organisation has, culture is something that an organisation is, while others claim that culture exists within an organisation.

The distinction between "good" security culture and "bad" culture suggests that there are some specific properties correlating with the safe operation of the enterprise.

The elements of company culture are: tradition, norms (directives, principles), system of values (ideas and images) and beliefs (human attitudes and their orientations, e.g. for market activities), as well as various creations of a given culture called artefacts, which are visible and aware on the outside (physical artefacts - material creations of a given culture, such as: art, technology, material objects; behavioural artefacts, such as ceremonies and rituals, and linguistic artefacts, such as the specific language of an organisation, myths and legends).

3. The need for research into the security culture in the organisation

A security culture plays quite an important role in any environment that creates social capital. The organisation's environment is also an important reference. In this environment it needs to be based on positive values indicating clear rules of conduct. Employees should have a conviction of the quality and universality of their work. Organisations are the place where the employee does his or her job, on the one hand, and should work on his or her personal and professional (specialist) development on the other. A positive attitude towards oneself translates into a friendly and favourable attitude towards others. This makes it possible to learn about one's own potential perceived as a source of life energy, self satisfaction and achievements. Internal calmness together with acquired knowledge and skills leads to innovation and creativity in creative solving of widely understood problems. These are benefits that result from the full use of the potential inherent in the culture of security. It should also be stressed that the use of a cultural perspective in an organisation's environment can foster a better understanding of many dimensions of human security among employees. Using the potential of a security culture to build broadly understood employee coherence allows reducing the specific gap between growth and the ability to meet security needs. This will enable employees to counteract failures and use opportunities and challenges to their advantage.

Recently, there has been an increase in the number of accidents in organisations related to employees' non-compliance with security culture. It seems that organisations are a special place to promote and develop knowledge, technology and security culture. Therefore, it is important to assess the key aspects of security culture related to occupational risk assessment, prepare employees for emergencies, the health and security training process, preventive health protection and attitude to threats. Health and security training and evacuation exercises in many organizations are rare. Organizations care for the safety of their employees differently, while educating them little in the field of health and security and fire protection, first aid and crisis management.

The risks posed by employees in the organisation may come from three sources. First, incorrect behaviour of the employee himself. Disregard for the threat and instructions, insufficient focus on the activity, unexpected surprise, haste. Sometimes, it is inappropriate for an employee to behave arbitrarily, including: performing activities without removing hazards in the danger zone, entering or entering the danger zone without making sure that there

is no danger, not using personal and collective protection equipment and safety devices. The impact of negative psychophysical factors may deteriorate an employee's state of health, reduce their intellectual performance or even cause illness. Thirdly, from the so-called social work environment (bad interpersonal relations prevailing in the organisation). Violence, aggression, emotional blackmail, verbal insults, racism, bullying, sexual harassment can lead to physical and mental illness. Depression, concentration disorders, anxiety, neurosis, suicidal thoughts - these are just some of the ailments accompanying the bullying of employees. Long-term tension can also result in heart, circulatory, stomach or intestinal diseases, shortness of breath, headaches and often permanent insomnia (Bernardi, 2019).

It should be stressed that the need to research the security culture in an organisation is also influenced by the improvement of working conditions, especially in practical (specialist) work. Thus, achieving optimal working conditions and reducing the risk to an acceptable level will improve security. However, ensuring adequate working conditions is not enough, as much depends on the employees themselves, both mentally and practically. If technical and system solutions for security are already in place in organisations, we can only achieve an improvement in security culture. Creating a high security culture among employees requires the organisation to be seen to be committed to security and life and health protection. Special attention to the development of a security culture deserves training to create the right attitudes and raise awareness among employees as part of a health and security culture. A high security culture significantly reduces the number of accidents at work, and training in this area makes it possible to raise the awareness of university staff in the field of occupational health and security and reduce accidents.

There are three main factors that contribute to the emergence of organisational security cultures: management commitment, responsibility and awareness (Bulgurcu et al. 2010; Herath and Rao 2009). Management commitment can be measured by perceiving management's efforts to achieve organisational goals, which is reflected in an organisational culture based on employee engagement and adapting goals to effectiveness (Knapp et al. 2006).

Views on the culture of the organisation were built over many years and were influenced by case studies that the authors implemented in various aspects of security, including security management and culture (Shedden et al., 2006; Maynard, Ruighaver, 2006, Koh et al.). In some case studies, the safety security culture was observed as part of understanding other aspects of safety security, while in others particular emphasis was placed on the safety security culture of the organization. Our research concerned an organisation where decision making in terms of security was dispersed and loosely controlled.

4. Security culture in the organisational behaviour of employees

Men prevailed among the surveyed employees, who constituted over 83% of the respondents (25 people). The structure of employees is similarly distributed by gender (see figure 1).

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810

Fig. 1. Age structure of respondents

The dominant group of employees in terms of age are middle-aged people, i.e. 31-40 years of age - about 37%, the second group are young people up to 30 years of age - about 33%. In terms of education, the dominant group of respondents were people with secondary education. Among 30 respondents - 24 were with secondary education i.e. 80%, five with higher education (17%). Among the surveyed employees there is one person with vocational education. Among the employees, 20% had seniority of up to five years, of which 13% had up to five years and 7% had up to one year. The most numerous group were people working from 6 to 10 years, - about 47%. A large group was made up of people who had worked in the company for 11 years or more - 10 people among the respondents - i.e. 33% (see figure 2).

Fig. 2. Seniority of respondents

Among the respondents there were 10 people who held managerial or managerial positions in retail outlets. The remaining 20 people were sales department employees and employees employed in the company's headquarters.

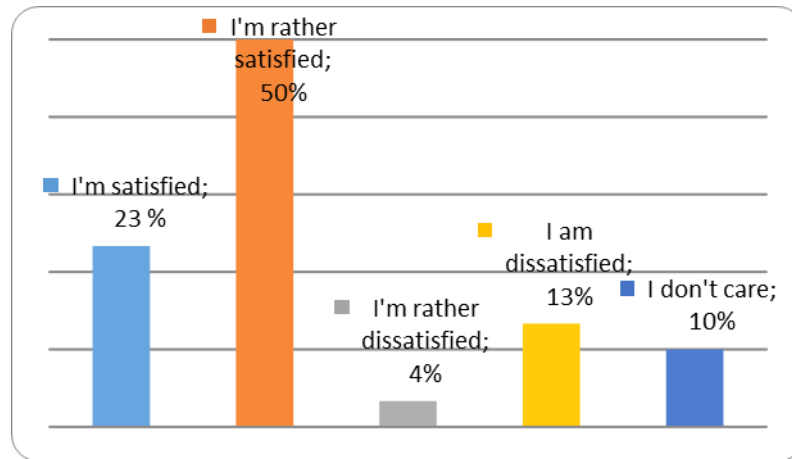
The next question asked to the employees was the question related to satisfaction with their work. 73% of people answered that they were satisfied or rather satisfied. With only 23% fully satisfied, the remaining 50% were rather satisfied. About 17% were dissatisfied with their work. Those who did not have an opinion or did not care - 10%. The figure 3 below shows these relationships.


Fig. 3. Satisfaction with the work performed

The next question was about how to understand the definition of organisational culture. The figure 4 below shows the distribution of answers.

Figure 4. Understanding the definition of organisational culture

A very large percentage of respondents did not know what it was and how it defined the concept of organisational culture. Over 43% of the respondents were unable to answer what organisational culture is. 23% answered - that it is a set of values of tradition, beliefs, attitudes that function within the company. 17% each considered that there are rules of belonging to a given company and that there is a way of management, organisational climate and interpersonal relations.

As almost half of the people did not know what organisational culture was in the next question about the detailed character of organisational culture, whether it is positive or negative, conservative or innovative, masculine/female or silane/weak respondents had a problem with answering this question. Most - 20 people answered that they did not know the answer to this question. Only 10 people - all managers were able to answer

the question. The scope of managers' answers about the nature of organisational culture is presented in the table 1 below.

Table 1. Nature of organisational culture according to the respondents

N.	Type of culture	Number of indications
1	conservative	10
2	bureaucratic	9
3	male	8
4	strong	8
5	female	2
6	pragmatic	1

Source: Own research

Most managers describe the organisational culture in Techzbyt sp. z o.o. as conservative, male, bureaucratic and strong. The next question concerned the influence of organisational culture on the functioning of Techzbyt sp. z o.o. Data on this subject is presented in the figure 5 below.
Figure 5. Understanding the definition of organisational culture

60% of those surveyed did not know if such an impact existed on their company. 33% of those surveyed said it was large and very large. The answers were mainly given by managers, the rest replied that it was not large - 7% and they were most likely administrative staff.

In response to the question concerning the values of Techzbyt sp. z o.o. most of the respondents (50%) replied that the company is profit-oriented. And 1/3 of the respondents replied that they respect and care for the employee. A large percentage of those surveyed were not able to answer with what their company is aiming at. This information is illustrated by the figure 6 below.

Fig. 6. Evaluation of the values that Techzbyt is guided by

The respondents in the next question defined the factors that influence the development of the company. The answers were quite diverse. Only one factor received more than 30% of the indications. It concerned customer loyalty. The employees are aware that without customers the company will not function and thus will not develop (see table 2).
Table 1. Factors that influence the development of the company

N.	Answers	number of people	%
1	Leadership	3	10
2	brand value	3	10
3	Reputation	1	3
4	knowledge of employees	5	16
5	Culture	1	3
6	Innovation	2	6
7	Communication	5	16
8	Customer loyalty	10	33
9	Total	30	100

A high response rate of 17% was achieved by communication and staff knowledge. Three answers were given for leadership and brand value. The answer in the sales company concerning innovation is surprising. One answer each was given to the reputation, which is derived from the question of brand value and culture - as a factor influencing the development of the company.

The next question was whether the loyalty and commitment of employees is influenced by the culture of the organisation. As most of the respondents did not know the definition of culture, negative answers were obtained. Most of the respondents replied rather not (43%). Only managers gave affirmative answers (34% in total), but not definitely affirmative answers (27%).

A positive aspect among the respondents is the knowledge of company strategy. The most. i.e. more than 90% of people know the company's strategy well or very well. Only 7% did not know the strategy to the end - giving answers rather not. A similar distribution of votes concerned the pleasant atmosphere at work. 40% of the

respondents answered definitely yes to this question. Another 53% rather yes. Only 7% of the respondents did not like the atmosphere at work - but answered rather not.

Since salespeople are obliged to wear special clothing with the company's logo in shops and company outlets, the question concerning the habit of wearing the logotype will be answered by 100% of those surveyed definitely yes (83%) and rather yes (17%). Those who answered yes are administrative employees who are not obliged to wear special clothing.

The next questions concerned the trainings organised by the company. The Management Board of Techzbyt sp. z o.o. has developed its own internal training program for its employees working in the sales department. Depending on the nature of work, they participate in various forms of training. The company organises cyclical, semi-annual conventions for its shop managers. During such conventions, the managers are acquainted with action plans for the coming months, but also participate in trainings organised by the Technical Service Department.   For employees - salesmen, trainings on customer service are organised once a year. It takes place in 3-4 turns per year. Each such turn is attended by one employee from a given store, so that the staffing of a given facility is ensured. During such one-day training, employees receive knowledge of customer service, nice looks and tidy clothes. They also learn about new products offered in stores and their properties. During such training, they learn what to offer customers and how to advise them on product selection.

The evaluation of this system has been satisfactory. The training programme is evaluated well by the employees. Most of the answers were rather yes, which was 83%, while 17% were very satisfied with the training system and what they achieved from it. The question of providing comments and ideas and opinions during the training is worse. Here, there are negative answers - rather not - but only - 17%. Due to the fact that there is no motivation system in Techzbyt sp. z o.o., the questions concerning the existence of motivation and its role in the organisation were negative. Only two people think that there is an incentive system. The remaining 28 replied that they were unlikely to (25 people) or definitely not (3 people). Also negative answers were given to the question concerning the organisation of sport and recreation events, because the company does not organise them. Another issue in the questions was communication. The respondents were supposed to answer what, in their opinion, is the communication in the company. According to the respondents, communication at Techzbyt is insufficient (26 answers), inconsistent (17) and official (22 answers). It goes from top to bottom (27 answers) and is written. It is significant that negative answers were also given by managers, who most probably do not make any changes in this direction. The survey asked a question about what the employees are rated highest for. Most of the people surveyed answered, concerning professionalism at the workplace. There were as many as - 43%, i.e. 13 people think so. Then it was focused on results - 7 people, i.e. 23%, answered this way. Only in the third place the respondents indicated their knowledge - 20% (i.e. 6 answers). Most probably, these were people working in administrative positions in accounting or technical department. The results are shown in the figure 7 below.
Fig. 7. Evaluation of the most evaluated areas of employees' functioning

The last question was what should be changed at Techzbyt. As far as changes in the way of management, control system and changing office equipment are concerned - the respondents did not answer (see figure 8).
Fig. 8. Indication of changes in the modes of operation of the tested function and baad

On the other hand, the respondents want mainly changes in the motivation system - 40% (12 people), the way of evaluating employees - 27% (8 answers). The same number of respondents want changes in the remuneration system. Two people want changes in the way training is conducted.

Conclusions

The research conducted in Techzbyt Sp. z o.o. allowed to determine the functioning of the organisational culture in this company, which has quite a significant impact on the level of security culture. The lack of information about elements of culture in this company is clearly visible. To a large extent, the middle management of the company is to blame. Employees do not know what the organisational culture is, and how to relate its meaning to security and what it is characterized and manifests and what elements it contains. Employees do not know how to define the concept of organisational culture, only some of the employees in managerial positions know what it is.

After the survey, the following statements can be summarised:
1. Lack of information on the organisational culture among the ordinary employees of retail outlets (sellers), only partial knowledge of this issue among the ordinary administrative staff.
2. Managers are better aware of their organisational culture. However, they do not inform their subordinates.
3. There is a belief among the staff that the management of the company is solely profit-making. According to the respondents, there is a low level of respect and not enough care for employees.
4. There is a low level of satisfaction with the incentive system and the level of remuneration. The incentive system does not exist at the level of regular employees. The main beneficiaries of this system are managers of shops and retail outlets who receive discretionary bonuses.
5. The company's existing training system is satisfactory, but can be improved by making changes to its organisation (concerns the way ideas and comments are communicated)
6. In the company, communication is very formal, only towards the employee manager, not the other way round. Most of them think that it is insufficient and inconsistent.
7. There is no employee appraisal system in the company which would contribute to the introduction of an incentive system and enable the best employees of retail outlets to increase salaries.
8. There is a high awareness of professionalism among employees, but due to the lack of a motivational system it does not release additional energy for new duties.

It can be concluded that the average employee - a salesman - does not know the organisational culture in his company is and what it is. At Techzbyt company, there is too little communication between middle management and employees in terms of providing information that is highly formalized. There is no system to motivate and support employees in their professional development. The main focus of the company's management is on earning the highest possible profit without taking too much care of the employee. Based on the research, it can be concluded that building a high security culture in the company is primarily favoured by the belief that security is a value connected with every objective of the organisation.

The research shows that most managers of retail outlets cannot properly communicate with the staff.
In order to better organise work and create a proper security culture it is essential that
- Managers better inform their subordinates about the elementary principles of organisational culture and elements of their own,
- Introduce an employee appraisal system on the basis of which to build an incentive system,
- Prizes should be related to efficiency and not to internship or other considerations not related to merit,
- Managers must recognise that employees have different motivations and talents,
- Managers should cultivate an efficient company culture,
- Introduce a system of two-way communication, not one-way communication,
- Improve the training system to enable employees to make their own comments and reflections, Enabling employees to develop and advance professionally.

Organisational culture is created by a set of standards, values and beliefs characteristic of a given organisation, to which employees apply and which determine the way of life of individuals and groups in the organisation. Whereas the security culture is an element of organisational culture. It is a product of individual and group values, attitudes, competences and behaviour patterns that determine involvement in activities related to security management in the organisation and affect the style and effectiveness of this management. The researchers

focused on one company, what is a research limitation. Nevertheless, we believe that further researchers can echo analysis of the case study and, ultimately, a gap of peculiarities of security culture will be filled in.

Abstract. The aim of the present study was to investigate the role of entrepreneurship education and entrepreneurial intention by adding the current data in the context of Indonesia. This study also involves some variables that predicted affect students' entrepreneurial intentions, including entrepreneurial self-efficacy and entrepreneurial attitude. The study design applied in this research was a survey method with a quantitative approach to help understand the relationship between variables. This study used a convenience random sampling technique to collect the information of students in several state universities in Indonesia. The participants of this study were students in the second and third-year study who enrolled in the course of entrepreneurship and education and actively participated in programs of entrepreneurship. This investigation confirms four hypotheses and rejects the two hypotheses proposed. In more detail, entrepreneurship education successfully influences entrepreneurial self-efficacy and students' attitudes toward entrepreneurship. However, it failed in promoting students' intention of being an entrepreneur. On the other hand, entrepreneurial self-efficacy has an impact on entrepreneurial attitude, while entrepreneurial attitude does not influence on students' entrepreneurial intentions. Lastly, from this study, it showed that entrepreneurial attitude insufficient in mediating entrepreneurship education and intention being entrepreneurs.

Keywords: entrepreneurial education; entrepreneurial intention; entrepreneurial attitude; self-efficacy

---

1. Introduction

An important question continually confronted by governments in both developed and emerging countries is how to incline the number of entrepreneurs. The fundamental rationale is that small and business provides new job opportunities that can contribute for economic development, economic growth and community wellbeing (Turkina & Thai, 2013; Hoz-Rosales et al., 2019; Tung et al., 2020). One way to escalate entrepreneurs is through entrepreneurial education program to ensure individual have adequate knowledge needed for preparing a business. Scholar have documented the role of entrepreneurship education as a driving factor to insight into entrepreneurship from the formal education side (Maresch et al., 2016; Gerba, 2015; Bae et al., 2014).

As was pointed the essential role of entrepreneurial education, Kourilsky and Walstad (1998) suggested to enhance the entrepreneurship education from elementary school to tertiary education, particularly on developing countries. Likewise, Indonesian government also promotes an entrepreneurship program for students, which intended to boost the number of entrepreneurs (Saptono et al., 2018; Purwana et al., 2019). The policy to increase the number of entrepreneurs in Indonesia is forecasted in two primary functions; accelerating the presence of prosperity and reducing the number of unemployed young people (Patricia & Silangen, 2016; Utami, 2017).

In the context of Indonesia, the unemployment rate in Indonesia by approximately 5.28 per cent is dominated by college graduates (Statistics Indonesia, 2019). Dealing with this issue, universities in Indonesia need to revitalize the implementation of entrepreneurship education. Furthermore, universities require a comprehensive model of entrepreneur education, covering targets, learners, content, methods, and evaluation by placing targets as a central component (Muwarni, 2016; Gautam & Singh, 2015). The lack of entrepreneurial intentions among college graduates needs to be concerned by the government. Entrepreneurial intentions can be seen from the willingness to work hard and diligently to achieve business progress, the willingness to bear the various risks associated with doing business in doing it, willing to take new paths and ways, willingness to live frugally and to learn from experience.

Accordingly, entrepreneurial intention among university students can be explained by several factors, including norms, self-efficacy, environment, education, and attitude (Maresch, 2016). Having already witnessed a review of this field, Uddin and Bose (2012) pointed out that the tendency to take risks, the need for achievement, education and the environment to start a business, job security is essential in determining student intentions. In acquaintance with entrepreneurship education, Zhao et al. (2005) found a positive correlation toward entrepreneurial intentions, particularly when this relationship works according to favourable perceptions of entrepreneurship. Wu and Wu (2008) noted educational factors that influenced attitudes toward and perceived behavioural control positively influenced student entrepreneurial intentions. However, from the study, it found that subjective norms did not significantly influence entrepreneurial intentions.

Based on the theory of planned behaviour (TPB), attitudes and perceived behavioural have a correlation, while subjective norms have a lower significance. A prior study by Zhang et al. (2014) demonstrated that education has no influence on intention, whilst knowledge also has no impact on individual ability. Samydevan et al. (2015) added that psychological, educational and cultural characteristics influence entrepreneurial intentions among students in Malaysia. In addition, Ferreira et al. (2017) stated that self-efficacy has a relationship with intention of being entrepreneurs. Meanwhile, Ogunleye and Osagu (2014) revealed that self-efficacy, achievement motivation, age and gender did not significantly predict entrepreneurial orientation. Gedik et al. (2015) indicated that three attitude variables towards entrepreneurship, role models, and entrepreneurship education courses contributed to

student motivation in entrepreneurship. Furthermore, Tong et al. (2011) found students would choose to become entrepreneurs as long as there was a need for achievement, family business background, and subjective influence.

This study contributes of the present study are three folds. First, it contributes to the existing litrerature on factors affecting students being entrepreneurs by enhancing variables self-efficacy and entrepreneurial attitude that is missing in the prior works. Second, the inevitable studies of entrepreneurship education and entrepreneurial intention have largely investigated across the world. For instance, Tung et al. (2020) in Vietnam and Philippines, (Maresch, 2016) in Ethiopia, Uddin and Bose (2012) in Bangladesh, while this study has been conducted in Indonesia. The focus on Indonesia is unique due to the fact that the lack of entrepreneurs although it has great market and resources (Eryanto, 2019; Saptono et al., 2019). Additionally, this study presents an insight into the mediating role of self-efficacy and entrepreneurial attitude in explaining students intention being entrepreneurs.

2. Theoretical background

2.1 Entrepreneurship Education

Fayolle and Gailly (2015) revealed that entrepreneurship education emphasizes on preparing business plans, how to get financing, business development processes, and small business management. The education provides knowledge about the principles of entrepreneurship and technical skills regarding business management. Wang (2004) found that the inadequate level of students' perception and knowledge on entrepreneurship before taking entrepreneurial education. Lee and Wong (2003) asserted that entrepreneurship education in tertiary institutions has a direct relationship in shaping the attitude of students in taking risks for the establishment of new businesses. For these reasons, entrepreneurship education must be designed in such a way as to have an impact on encouraging students' intention to become entrepreneurs.

In the literature, several prior studies have investigated the entrepreneurial education and intention being entrepreneurs in many countries. For instance, (Maresch, 2016) showed a positive correlation between those variables in Ethiopia. Indeed, in Bangladesh, Uddin and Bose (2012) found that entrepreneurship education influences students' entrepreneurial intention. The study of entrepreneurship education was also conducted in other countries in Vietnam and the Philippines (Tung et al., 2020). Also, Zhao et al. (2005) pointed out relevant implications that entrepreneurship education is positively related to entrepreneurial intentions, primarily when this relationship works according to favourable perceptions of entrepreneurship.

The entrepreneurial intention is measured by several indicators, including involvement in entrepreneurship programs on campus, starting self-employment after graduation, working with excellent partners after graduation and starting entrepreneurship if there is funding support (Autio et al., 2001; Kolvereid & Isaksen, 2006; Zhao et al., 2005). Furthermore, Turker (2009) proposed the indicator to measure intention, such as choosing the path of business rather than working for someone else, choosing a career as an entrepreneur, and planning to start a business. Meanwhile, Shapero and Sokol (1982) expressed that entrepreneurial intentions depend on three elements: a sense of desire, a tendency to act, and a sense of worthiness. A sense of desire is defined as the personal attraction of starting a business. Eligibility is considered understood as a belief in the ability to start a business, and a tendency to act refers to one's disposition to act decisively when faced with an opportunity.

In addition, a correlation between entrepreneurship education and self-efficacy have confirmed by Saptono and Wibowo (2018); Wibowo et al. (2018). Indeed, Keat et al. (2011) mentioned that the primary goal of entrepreneurship education is to change the views, behaviours, attitudes and intentions of students to understand entrepreneurship, have an entrepreneurial mindset, and later become successful entrepreneurs building businesses.

Similarly, Sizong et al. (2008) also argue that entrepreneurship education significantly influences a person's attitude to be an entrepreneur. Besides, the influence of entrepreneurship education and entrepreneurial attitude was documented by Ambad and Damit (2016); Lüthje and Franke (2003); Ozaralli and Rivenburgh (2016); Turker and Selcuk (2009); Yang (2013), which indicates that the entrepreneurial attitude has an impact on intention being entrepreneur.

H1:   Entrepreneurship education influences students' entrepreneurial self-efficacy
H2:   Entrepreneurship education influences students' entrepreneurial attitude
H3:   Entrepreneurship education influences students' entrepreneurial intention

2.2 Self-efficacy
In addition to entrepreneurial education, the formation of student entrepreneurial intentions is self-efficacy. According to King (2012), self-efficacy is the belief that someone can master a situation and produce various positive results. Self-efficacy helps people in various unsatisfactory situations and encourages them to believe that they can succeed. Self-efficacy plays a role in decision making, thought processes, and courage in taking risks. Every individual who has high entrepreneurial intentions will be able to stand alone, dare to make decisions, and implement goals to be achieved at their discretion. This shows that the higher the self-efficacy will lead to greater entrepreneurial intention (Ogunleye & Osagu, 2014). Several prior studies believed that self-efficacy will lead to the intention of being entrepreneurs (Ayodele, 2013; Guzmán-Alfonso & Guzmán-Cuevas, 2012), while the results of some researchers showed an insignificant impact between self-efficacy and entrepreneurial intention (Ferreira et al., 2017; Ogunleye & Osagu, 2014).

H4:   Entrepreneurial self-efficacy influences students' entrepreneurial attitude

2.3 The mediating Role of Entrepreneurial Attitude
Another significant aspect of intention being entrepreneurs is attitude. Keat et al. (2011) pointed out that students' entrepreneurial intention is affected by entrepreneurship education. Through the learning process on entrepreneurship, it will lead to changes in behaviours and interests of students in order to understand entrepreneurship and have an entrepreneurial mindset and later become entrepreneurs. Similarly, Wu and Wu (2008) confirmed that entrepreneurship education significantly influences an individual's attitude to be an entrepreneur.

Rosmiati et al. (2015) noted that attitude is an emotional readiness in some action on something appropriate or as something that is learned and how individuals react to situations and determine what is sought in life. The entrepreneurial attitude is the tendency to react adequately in responding to the risks that will be faced in business. Moreover, Gedik et al. (2015) viewed individuals who show a positive attitude towards entrepreneurship, are more likely to act as an entrepreneur and believe that entrepreneurship is not just a method of survival but a way to achieve self-actualization. Based on the previous theoretical studies and previous research, this study tests the following hypotheses.

H5:   Entrepreneurial attitude influences students' entrepreneurial intention;
H6:   Entrepreneurial attitude mediates the impact of entrepreneurship education on students' entrepreneurial intention.

3. Research objective and methodology

3.1 Empirical Study Design

The study design applied in this research was a survey method with a quantitative approach. The benefit of adopting this approach gains a detailed understanding of how entrepreneurial education, entrepreneurial attitude, and self-efficacy influence students' intention of being entrepreneurs (see figure 1). This study used a convenience random sampling technique to collect the information of students in several state universities in Indonesia, including Universitas Negeri Malang, Universitas Negeri Jakarta and Universitas Negeri Semarang. The fundamental reason is that those universities represent each region, Universitas Negeri Malang (East Java), Universitas Negeri Semarang (Central Java), and Universitas Negeri Jakarta (West Java). This study was conducted for about two months, from January to February. The participants of this study were students in the second and third-year study who enrolled in the course of entrepreneurship and education and actively participated in programs of entrepreneurship. The leading researcher distributed 300 questionnaires, and 290 were returned, a response rate of 96.7 per cent. The majority respondent of this study was female by approximately 65 per cent, which reflected a higher proportion than male.
Figure 1. Theoretical Framework

Source: authors (2020)

3.2 Measurement and Data Analysis

The survey questionnaires used to collect information about entrepreneurial education (EE) were adapted from Souitaris et al. (2007), and Denanyoh et al. (2015). Besides, the entrepreneurial intention (EI) was measured by eight items instruments adapting from Zhao et al. (2005); Kolvereid and Isaksen (2006); Linan & Chen (2009). Meanwhile, to measure entrepreneurial self-efficacy (ES), we adapted 14 items developed by Ferreira et al. (2017); Zhao et al. (2005). Lastly, entrepreneurial attitude (AE) was measured by nine items of instruments developing by Yang (2013); Linan and Chen (2009). This study used a 5-point Likert scale in an attempt to gauge responses comprehensively.

This study engaged two stages of data analysis: exploratory factor analysis and confirmatory factor analysis. The initial test is aimed at validating, exploration dimensions, and maintaining strong indicators by using SPSS version18 (Allen & Bennett, 2010). A construct is said to be reliable if it has an alpha Cronbach (α) score equal to or higher than 0.6 (Hair et al., 2006). The next test was the confirmatory factor analysis (CFA) AMOS version 18.

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810

The model tested needs to satisfy several criteria and a cut-off value, including p-value (probability) > 0.5 to obtain a fit model (Schermelleh-Engel et al., 2003). Furthermore, CMIN / DF values <2 (Tabachnick & Fidell, 2007), CFI> 0.95 (Hu & Bentler, 1999), and RMSEA ≤ 0.05 (Hu & Bentler, 1999).

4. Results and Discussion
4.1 Resuts

Based on the initial test using exploratory factor analysis, it is known that from a total of 43 factors, including entrepreneurship education (12), entrepreneurial intention (8), entrepreneurial self-efficacy (14), and entrepreneurial attitude (9). Each variable has a loading factor of 0.621 to 0.917, and a Cronbach's alpha between 0.678 to 0.906. Moreover, based on SEM calculation results to check the theoretical framework and fitted models, a probability score of 0.073 is obtained, a CMIN / DF score of 1.324, a CFI score of 0.971, an FMIN score of 0.202 and an RMSEA score of 0.034.
Figure 2. Results of the Structural Equation Research Model

Source: authors (2020)

Table 1. Result Summary of Hypotheses testing

				Estimate	*S.E.*	*C.R.*	*P*	**Result**
H₁	EE	→	ES	0.438	0.106	4.131	***	Significant
H₂	EE	→	EA	0.520	0.128	4.054	***	Significant
H₃	EE	→	EI	0.144	0.080	1.795	0.073	Insignificant
H₄	ES	→	EA	0.322	0.105	3.067	0.002	Significant
H₅	EA	→	EI	0.358	0.102	3.515	***	Significant
H₆	EE→ EA→ EI = b score 1.601							Insignificant

Source: authors (2020)

Note: EE = entrepreneurial education; ES = entrepreneurial self-efficacy; EA = entrepreneurial attitude; EI = entrepreneurial intention

Table 1 informs the summary of the hypothesis testing between variables. In general, the variables tested were satisfied with the model. In more detail, H_1, H_2, H_4, and H_5 were significant, with the C.R score is 4.131, 4.054, 3.067, and 3.515, respectively. These results, according to Hair et al. (2006), the C.R value of each of these hypotheses is significant because of $\pm$ 1.96. In contrast, H_3 and H_6 were not significant because of the C.R value of 1.795 and 1.601, respectively.

4.2 Discussion

Based on the previous analysis, this study has successfully addressed the six hypotheses proposed. The result of this study is relevant to the previous study by Fayolle and Gailly (2015); Laviolette (2012); Sánchez (2013); Von Graevenitz (2010). Indeed, the finding of this study agreed with previous papers in Indonesia context by Purwana and Suhud (2017); Saptono and Wibowo et al. (2018). The discovery of the study confirms the importance of entrepreneurship education. In order to improve students' self-efficacy, entrepreneurship education does not only cover at the theory of entrepreneurship, but also the practice of how to become an entrepreneur. The universities should hold various seminars related to entrepreneurship, by presenting practitioners and alumni who are already successful entrepreneurs. Their best practice will inspire students, as well as foster their self-efficacy so that the entrepreneurial intention is more definite. The practice of entrepreneurship should cooperate with various government and private agencies, so students increasingly understand how to build business relationships/business networks, market products, and find additional capital for businesses.

The second set question aims to understand the relationship between entrepreneurship education and entrepreneurial attitude. This result corroborates the findings of a great deal of the previous work by the Asia region (Bae et al., 2014; Ozaralli & Rivenburgh: 2016; Peng, Lu, & Kang, 2012). Also, this finding supports several prior studies, which conducted in Indonesia by Saptono and Wibowo (2018); Wibowo et al. (2018). Indeed, Keat et al. (2011) mentioned that the primary goal of entrepreneurship education is to change the views, behaviours, attitudes and intentions of students to understand entrepreneurship, have an entrepreneurial mindset, and later become successful entrepreneurs building businesses. Similarly, Sizong et al. (2008) also argue that entrepreneurship education significantly influences a person's attitude to be an entrepreneur. The majority of studies found that entrepreneurship education plays an essential role in building student entrepreneurial attitudes. Lee and Wong (2004) in their study findings reinforce Ajzen's (1991, 2002) with the theory of planned behaviour (TPB). Keat et al. (2011) asserted that the primary goal of entrepreneurship education is to change the views, behaviour and interests of students. Hence, they understand about entrepreneurship, and have an entrepreneurial mindset and later become successful entrepreneurs who build new businesses so they can open new job opportunities. Additionally, student attitudes can be improved by entrepreneurship education, increasing the practice of entrepreneurship (George & Bock, 2011; Souitaris et al., 2007). Through practice, entrepreneurship education enables students to have a lot of knowledge and practice it directly. Such an educational model will further strengthen the entrepreneurial attitudes of students while increasing their entrepreneurial intentions (Wu & Wu, 2008).

However, another finding of this study demonstrated that entrepreneurial education does not impact students' entrepreneurial intentions. This finding is in opposite with antecedent studies in Europe and Asia countries (Maresch et al., 2016; Barba-Sánchez & Atienza-Sahuquillo, 2018; Fayolle, 2015; Sánchez, 2011; Souitaris et al., 2007; Zhang et al., 2014) which found that entrepreneurship education influences entrepreneurial intention. However, our findings are relevant to the data from Statistics Indonesia (2019), which stated that the number of unemployed in Indonesia is 5.28 per cent, with the highest number contributed by universities. It implies that entrepreneurship education from elementary to tertiary levels has not been effective in growing student

entrepreneurial intentions. Therefore, universities in Indonesia need to revitalize the implementation of entrepreneurship education. Moreover, the university's efforts to grow entrepreneurship require a comprehensive entrepreneur education model that includes targets, learners, content, methods and evaluation by placing targets as a central component (Muwarni, 2016).

Entrepreneurial self-efficacy has an impact on students' entrepreneurial attitude. This study supports evidence from previous observations by Ayodele (2013); Guzmán-Alfonso and Guzmán-Cuevas (2012); Samydevan (2015); Ferreira et al. (2017), which states that the TPB component influences entrepreneurial attitude and entrepreneurial intention, where one component of TPB is self-efficacy. However, this outcome is contrary to that of Ogunleye and Osagu (2014), that remarked self-efficacy does not significantly influence entrepreneurial attitude and entrepreneurial intention. Entrepreneurial self-efficacy contributes to entrepreneurial attitudes. Our findings are relevant to Bandura (1989), who mentioned that self-efficacy can successfully carry out the desired behaviour, has a robust link with entrepreneurial attitudes and intentions. This finding is reinforced by and Conner et al. (2011) which states that self-efficacy correlates very strongly to one's intentions and attitudes.

The fifth question in this study sought to determine the influence of entrepreneurial attitude toward students' entrepreneurial intention. This result is in accord with recent studies by Ambad and Damit (2016); Lüthje and Franke (2003); Ozaralli and Rivenburgh (2016); Turker and Selcuk (2009); Yang (2013) indicating that the entrepreneurial attitude has an impact on intention being entrepreneur. Indeed, this finding agrees with prior studies by Utami (2017), which stated that entrepreneurial intention is influenced by entrepreneurial attitude, subjective norms, and intentional behaviour control. Gallyn and Waspada (2012) stated that the variable attitude of entrepreneurial students has a positive influence on entrepreneurial intentions. Indeed, Keat et al. (2011), entrepreneurship education became a compelling scenario in shaping entrepreneurial attitudes. Because, the main objective of entrepreneurship education is to change the views, attitudes and interests of students to understand about entrepreneurship, and have an entrepreneurial mindset and later become successful entrepreneurs who build new businesses so they can open new job opportunities. This is relevant to the findings of Sizong et al. (2008) that entrepreneurship education significantly influences a person's attitude to be an entrepreneur, while entrepreneurial attitudes significantly influence entrepreneurial intentions.

The last question in this research was intended to understand the role of entrepreneurial attitude. For this finding, entrepreneurial attitude failed in mediating the impact of entrepreneurial education and students' entrepreneurial intention. This finding is contrary to previous studies which have suggested Lüthje and Franke (2003); Ozaralli and Rivenburgh (2016); Von Graevenitz et al. (2010); Yang (2013) and Zhang et al. (2014) that entrepreneurial attitude as a component of TPB mediates the effect of entrepreneurial education on entrepreneurial intention. Therefore, it can be stated that the implementation of entrepreneurial education in Indonesia has not been effective in influencing both directly and indirectly on entrepreneurial intention. This indicates that entrepreneurship education in a number of universities in Indonesia has not been effective in shaping attitudes and intentions. The data from Statistics Indonesia (2019) states that the majority of tertiary education graduates in Indonesia are afraid to take risks and tend to choose to become a private employee, civil servant, or state-owned company employee as their career choice. These conditions indicate that the intention to become an entrepreneur after graduating into a bachelor becomes a low-level entrepreneur. A practical step in overcoming this phenomenon is to revitalize entrepreneurial education to be more comprehensive: covering targets, learners, content, methods and evaluations by placing targets as central components. Entrepreneurship education must be an entrepreneurial education, where principles and methodologies are applied towards the formation of life skills for students through an integrated curriculum developed at the university. This is important considering that

entrepreneurship education obtained during college will be the essential capital for students to start and build a new business.

Conclusions

The present study aims to examine the relationship between variables, including entrepreneurial education, self-efficacy, entrepreneurial attitude, and intention being entrepreneurs. This investigation confirms four hypotheses and rejects the two hypotheses proposed. In more detail, entrepreneurship education successfully influences entrepreneurial self-efficacy and students' attitudes toward entrepreneurship. However, it failed in promoting students' intention to being an entrepreneur. On the other hand, entrepreneurial self-efficacy has an impact on entrepreneurial attitude, while entrepreneurial attitude does not influence students' entrepreneurial intentions. Lastly, from this study, it showed that entrepreneurial attitude insufficient in mediating entrepreneurship education and intention being entrepreneurs.

Taken together, these results suggest that universities need to design and implement various activities to encourage lecturers to apply a variety of creative and innovative learning methods and models, providing facilities and infrastructure to support entrepreneurial activities to create an entrepreneurial attitude and entrepreneurial intention. Furthermore, entrepreneurship education must also be revitalized, especially the curriculum, strategies, methods, facilities, and infrastructure, as well as the learning environment. This is so that entrepreneurship education can effectively influence student entrepreneurial intention. The most important limitation lies in the fact that the data was collected in three state universities in Indonesia, which the findings cannot be generalized to represent real conditions in all universities. The suggestion for further studies, it can develop a study with a broader area, for example, non-educational public universities with more complex data obtained and can be used as a basis for stakeholders in implementing policies related to increasing the number of entrepreneurs in Indonesia.

Abstract. Coworking practices have proliferated around the world being embraced not only by remote workers, start-up employees and freelancers but also by larger organizations. Coworking spaces in public libraries, business districts and other urban spaces, herald profound changes for the way workspaces are used in cities. The study takes an integrative approach to investigate the economic and socio-cultural implications of coworking trend for smart cities, their ecosystems and the use of urban public spaces. The study examines these issues by studying motivations and challenges of providers and users of coworking spaces. Thirty coworking spaces in urban areas across Australia were studied and thirty-four semi-structured interviews were conducted with both providers and users of the coworking spaces. The findings suggest that coworking spaces play an important role in building communities and developing social and cultural ties. From urban space and environmental perspectives, coworking spaces are likely to contribute to urban mobility and sustainability. From an urban economic perspective, coworking spaces provide a collaborative environment and often a breeding ground for entrepreneurship. Entrepreneurship is one of the most salient themes in the coworking spaces as found in this study. These findings will inform urban policy makers and help them better understand and tap into the source of civic entrepreneurship derived from coworking spaces.

Keywords: coworking spaces; smart cities; ecosystems; entrepreneurship; urban planning; public spaces

1. Introduction

Public spaces in urban areas as part of urban planning and urban governance have attracted extensive research interest over the last 20 years from various perspectives (Ravazzoli and Torricelli, 2017). For instance, architects and urban planners are interested in public physical space and people; urban sociologists study the role of public spaces in building social relations; and political scientists look into the use of public space for civil engagement and democracy. From a socio-cultural perspective, public spaces are considered places for social interaction, playing a central role in the creation of inclusive communities (Costamagna et al., 2019). Coworking spaces have been defined as 'shared workspaces utilized by different sorts of knowledge professionals, mostly freelancers, working in various degrees of specialization in the vast domain of the knowledge industry' (Gandini, 2015, p. 194). They can be referred to as a type of public space since they are 'publicly accessible places where people go for group or individual activities' (Carr et al., 1992, p. 50).

Although the concept of contemporary coworking originated in 2005 in San Francisco, it is only in the past few years that co-working spaces have become a striking and visible feature of metropolitan (Gandini, 2015; Nathan, 2017). Coworking practices have proliferated around the globe being embraced not only by remote workers, start-up employees and freelancers but also by larger organizations. A recent estimation shows that there are 14,411 coworking spaces in the world today with the number predicted to rise to 5.1 million by 2022 (Amador, 2018). Coworking spaces, according to Bounchen et al. (2018), generally have four distinct archetypes: the corporate, the open corporate, the consultancy, and the independent coworking spaces:
- Corporate coworking spaces are created by firms for their employees as a novel avenue for creativity, innovation and intrapreneurship;
- Open corporate coworking spaces are open both to internal and external users to encourage innovation and creativity among internal users and between internal and external users;
- Consultancy coworking spaces are usually created by consulting firms to organize and manage projects, relationships and networks with externals; and
- Independent coworking spaces offer membership to the public. They are mostly located in public libraries, business districts and other urban spaces and are characteristically open for public use.

For the purpose of this study, we refer to coworking spaces as urban public spaces which are aligned with ecosystem initiatives for the development of smart cities. There is a growing body of empirical evidence that some city governments support the growth of coworking spaces through public funding and/or offering public spaces such as city council buildings and public libraries (Mariotti et al. 2017). This reflects the importance of coworking spaces to urban governance and urban planning in those cities. Although co-working spaces have attracted considerable media and property market attentions (e.g. Cheung, 2018), research on co-working spaces is still developing as the trend grows. To the best of our knowledge, limited empirical research has been published to answer the important questions such as: what are (or could be) the economic and socio-cultural implications of co-working trend for smart cities, their ecosystems and the use of urban public space? How should urban policymakers react to the trend?

Smart cities are expected to be a driving force for innovation and entrepreneurship from an economic and business perspective (European Commission, 2019). However, smart cities can transcend the economic and corporate agenda to include social inclusion from cultural and social perspectives. The rise and growth of coworking spaces has brought the possibility of a new model of work in an environment of collaboration, openness and community where innovation and entrepreneurship thrive, and new fabrics of social culture develop. In this regard, an integrative approach is needed to study the rise of the coworking spaces and its implications for smart cities

planning and governance. This study seeks to address these important issues through a qualitative study of thirty co-working spaces. The findings of the study could have important implications for the planning of smart cities as well as contributing to the burgeoning literature on smart cities research.

The following section reviews the relevant literature on smart city and coworking space. Research questions are raised from this review. The methodology to address these research questions is then outlined. The findings are then presented, followed by a discussion of its research implications as well as the contributions and limitations of the study and directions for future research before we conclude the paper.

2. Literature Review

Smart cities

The smart city movement started in the 1990s (Letaifa, 2015) and has recently gained momentum in urban governments' planning in many countries at various levels – local, state and national (Albino et al., 2015). Research on smart cities often touches on four areas: the technological aspect (e.g. the technological infrastructure and support network for building smart cities); the socio-cultural aspect (e.g. citizen engagement); the political-institutional aspect (e.g. government support and policies); and the economic-business aspect (e.g. business models and profitability). It is generally agreed that the objective of smart cities is to enhance economic growth and social development through innovations in technology and heightened collaboration (Sarma and Sunny, 2017). However, some research also criticizes the concept of smart cities for its narrow epistemological perspective and its corporate agenda that primarily reflects the interests of multi-national consultancies and technology companies (Marvin et al. 2015; Tompson, 2017).

Research shows that smart cities rely on a smart city ecosystem to survive and thrive. Sarma and Sunny (2017, p.848) define a smart city ecosystem as a set of interconnected actors, such as agents (entrepreneurs), decision makers (e.g. policymakers and bureaucrats), framers (e.g. technology providers, supplier networks, and markets), and constituents (e.g. citizens, investors, and labour). We concur with this definition and argue that ecosystems go far beyond a diverse set of actors and networks. The smart city ecosystems should also include processes and systems, policies and governance that support smart city initiatives and development. Research indicates that a paradigm shift towards a more dynamic and open architecture is taking place in smart city governance (Mandeli, 2019). Cooperative governance and private and public partnerships are replacing traditional silo-based governance approaches. Citizens' involvement and community engagement in smart city development becomes an important aspect of discourse reflected in policy statements (European Commission, 2019; Trencher, 2019) and smart city strategies, and an area viewed as critical in smart city initiatives and research agendas (UNESCO 2019; Marek et al., 2017). Smart cities are about smart people. While smart technologies play a key role in making cities connected and digitalized, it is people who drive, create and take up technologies. Therefore, the success of smart cities lies in the creation and development of their people. Human and social capital are considered as the key pillars of the ecosystems, which smart city strategies seek to develop and nurture. Angelidou (2015) recommends that dedicated areas are needed within smart cites, where people can collaborate and engage in innovative activities that may lead to the development of human and social capital. Such areas are referred to coworking spaces.

Coworking space

Coworking practice has become a new model of workplaces in today's collaborative and sharing economy (Botsman and Rogers, 2011; Avdikos and Merkel, 2020). Many start-ups and some larger companies such as Woolworths, Accenture and LG Electronics have embraced the coworking space concept (Office Hub, 2018) because of the merits of collaborative working environment and the cost-effectiveness in terms of flexible leasing terms (Zhou, 2019). Public libraries are a popular form of coworking space. According to the president of American Library Association, many libraries in the US are being re-invented into modern community spaces, offering free coworking spaces for growing numbers of entrepreneurs, for whom they are better alternatives to coffee shops and a much cheaper option than hiring a desk in commercial coworking spaces like WeWork (Krueger, 2019).

Research on coworking spaces from both the perspectives of academic and practitioners has flourished over the past decade (Gandini, 2015). Based on a relational constructionist lens, Garrett et al. (2017) explore how members of a coworking space work together to co-construct and sustain a sense of community through their daily interactions. The study found that the sense of community was achieved through three overlapping interactions – endorsing, encountering, and engaging among members working in the coworking spaces.

Coworking spaces have also the benefits of work flexibility, serendipitous encounters with like-minded people, idea generation and sharing, business networking, and a relief from loneliness of working from home (e.g. King. 2017; Garrett et al., 2017). Mariotti et al's (2017) study investigates the location patterns of coworking spaces through a case study of Milan, Italy and assesses their effects on the urban context. The findings suggest that the participation of workers in coworking spaces contributes to local community initiatives, urban revitalization trends, and micro-scale physical transformations. The study of Bueno et al (2017) suggests that coworking spaces are likely to increase productivity through offering collaborative networks and a dynamic ecosystem to foster innovation.

However, critiques of coworking spaces question a somewhat self-proclaimed and often overenthusiastic evaluation of positive outcomes from coworking spaces (Gandini and Cossu, 2019). From an economic and business perspective, the study of Moriset (2014) points out the risks of possible 'coworking bubbles' driven by the profitability concerns. The study of Bounchen et al. (2018) analyses the cooperative tensions in value creation and appropriation in various types of coworking spaces.

The mixed reactions to the concept and practices of coworking spaces warrant better understanding of the trend. Moreover, what roles do coworking spaces play in smart city ecosystem in general and in entrepreneurship in particular. These questions remain largely underexplored in the current literature of either smart cities or entrepreneurship. As pointed out by the study of Mariotti et al (2017), empirical evidence and critical analysis are limited about the role of coworking spaces in smart cities, their ecosystems and the use of urban public space. We seek to address the gap in an integrative way through investigating the actual and potential economic (in the form of entrepreneurship) and social-cultural impacts of coworking spaces on urban planning and their residents.

Linking coworking spaces to smart city ecosystems

Over the past decade, research on smart cities has grown exponentially and expanded to multidisciplinary fields, integrating a range of perspectives (Kummitha and Crutzen, 2017; Trencher, 2019). There has been over 200 percent increase in publication volume on smart cities since 2009 (Ojo et al. 2015). The extensive review of the literature on smart cities conducted by Meijer and Bolivar (2016) reveal three common foci that are dominant in extant smart city research, namely, technological focus, human resource focus and governance focus. An international comparative study found that from a leadership perspective, smart cities can be seen as digital government, a digital driver for economic growth, an open platform for digital socio-political innovation, and an open platform for the digital economy (Sancino and Hudson, 2020). For the purpose of this study, we take an integrative approach to the concept of smart cities and view and discuss it from economic, political, social and cultural perspectives.

From an integrative perspective, smart cities are built on a robust ecosystem which should include an innovation environment that nurtures and supports smart cities, including smart people, leadership, strategies and policies, human and social capital, an integrated IT system and a collaborative and open culture (Appio et al, 2019). For example, smart city programs are designed to provide open channels to engage citizens and stakeholders and solicit inputs on the viability of smart city solutions and services in real life contexts (Meijer and Bolívar, 2016). The collaboration among the cities' residents, businesses and public sector is seen as a source of new and effective knowledge production and as a precursor for the development of open knowledge and innovation ecosystems. The smart cities ecosystem is not simply about technology but about culture, people, strategy and governance (Mora et al., 2019).

In this study we seek to understand more about what role coworking spaces play in the context of smart city ecosystems, how they work, the purposes and motivations of running and using coworking spaces, the perceived and realized outcomes of the coworking spaces and the key issues and challenges facing both the supply and demand sides. Hence, this study addresses the following research questions:
   • What drives engagement with coworking places?
   • What are the issues and challenges of coworking places?

3. Methods

To answer the research questions, we followed a qualitative design, arguing that a qualitative methodology allowed us to develop an in-depth understanding of the experiences of both users and providers of the coworking spaces studied and the context in greater detail (Yin, 2011). In line with the qualitative design, we employed semi-structured interview method, which provided consistency of questioning across interviews while having the flexibility to explore areas of interest in greater depth.

Sample

We selected 30 coworking spaces in urban areas across Australia, namely, Perth, Sydney, Melbourne, Brisbane, Adelaide, Hobart, Darwin and Canberra to cover all the major cities in Australia. The selection of Australia for the case study was mainly for three reasons: (1) Australia has been one of the leading countries in smart city transformation (KPMG, 2019); (2) Australia embraces a strong growth in coworking spaces (Cheung, 2018), with coworking spaces having grown by 297 to 309 per cent between 2013 and 2017, and the recent forecast estimates

a tripling in coworking spaces by 2030 (Cheung, 2018); and (3) leading researchers have been intensively involved in smart city projects in Australia.

The key criteria for the selection of coworking spaces included: a wide range of urban locations, a minimum of one-year operation of coworking spaces to see some outcomes, and a mix of private and public ownerships. Another important selection criterion was that the coworking space must be open to the public as this study has been intended to inform evidence-based policies and strategies concerning the public use of urban spaces.

Data collection procedure

Primary and secondary data for this study was collected during a 6-month period between October 2017 and April 2018, mainly from three sources: (1) extensive research on the websites of every coworking space studied; (2) semi-structured interviews with both coworking spaces providers (owners and/or operators) and users; and (3) site visits to some coworking spaces in Perth. In addition, some of our team members spent several days working in some of the coworking spaces to get first-hand experience.

As described in the previous section, a total of thirty-four semi-structured interviews were conducted with both providers (10) and users (24) of the thirty coworking spaces studied between October 2017 and April 2018. The interviews were conducted either face-to-face or via Skype with the participants in the coworking spaces they were associated with. The interviews took between half an hour and one and a half hours, with the average being close to one hour. All the interviews were tape-recorded and transcribed for analysis. The primary objectives of the interviews were to find out the actual and potential impacts of coworking spaces on users and the challenges and issues the coworking spaces had been facing. From the findings we sought to answer research questions about the roles of coworking spaces in innovation ecosystems of smart cities in economic and socio-cultural terms as well as their implications for future urban planning and governance. Therefore, our interview questions centred around:
- Motivations for providers and users
- Key challenges for providers and users

To ensure a robust and fair representation of stakeholders, we selected participants purposively based on their involvement in coworking spaces, their job type, managerial position, and industry/business sectors. Contact details and some of the demographic information about the participants were found mainly on the company websites of coworking spaces and through contacts during our site visits. After approaching 45 prospective participants by email and telephone, and in person, 34 of them agreed to be interviewed.

Table 1. Summary of demographics of *participants* in the interviews (N=34)

Variable	Provider (N=10)	29%*	Variable	User (N=24)	71%*
Gender	Male	70	**Gender**	Male	67
	Female	30		Female	33
Age	25-40	30	**Age**	25-40	46
	41-59	60		41-55	29
	60+	10		56+	25
			Occupation	Freelancer	17
Position	Founder/owner	70		Entrepreneur	42
	Manager**	30		Remote worker	8
				Student	13
Industry	Government	20		Digital nomad	4
	University/ Tertiary Institution	40		Local workers	8
	Business Services	20		Other	8
	Resources	10	**Industry**	Resources	8
	IT	10		Business Services	21
				Retail	4
Education	Postgraduate	40		Creative	4
	1st Degree	20		IT	25
	Undergraduate/ Tertiary	20		Tourism and Hospitality	8
	Non-Tertiary	20		Education and Health	8
			Education	Postgraduate	17
				1st Degree	33
				Undergraduate/Tertiary	29
				Non-Tertiary	21

Note: * Figures are percentages of demographics. **Manager category does not include owner or founder.

Table 1 presents a summary of the demographics of the participants in our interviews. We interviewed two groups: 10 providers and 24 users in order to get a comprehensive view of coworking spaces studied. In terms of the gender of the participants, the majority among both providers and users are male. In terms of age group, most of the providers we interviewed aged between 41 and 59. By contrast, the users were youth, millennials, middle-aged, and retirees, with a majority aged between 25 and 40. Most of the providers (70%) were funders and owners with a range of industry backgrounds. We found that users' backgrounds were more diverse, covering various industries and professions. Among the users, the largest group (42%) were entrepreneurs, followed by self-employed freelancers (17%) who did not see themselves as either entrepreneurs or students (13%). Among the participants, a small number of remote workers were employed by non-local companies. The rest were local workers - employees of local companies, and digital nomads from overseas. The 'other' category included retirees and local residents who were not employed at the time of interview. Overall, the users interviewed corresponding largely with the member profiles of the coworking spaces studied.

Data analysis

We adopted the data analysis process of Miles and Huberman (1994) which involves three concurrent sub-processes: data reduction, data display, and the drawing of conclusions. The data reduction that we conducted included qualitative content analysis of website contents (secondary data) to understand the background of the co-working spaces studied and the primary data of transcripts and notes from interviews. A theme coding system (using theme as a coding unit) was employed in the data reduction process. Accordingly, the large amount of data was coded and categorized into key themes identified through the repeated reviewing and comparing of data (Minichiello et al. 1990). Appendix presents a snapshot of our data display and the key themes from the interviews.

4. Findings

Coworking space - location, size, user profiles, ownership and business models

Table 2 summarizes the key profiles of the 30 coworking spaces we studied. In terms of geographic location, the sample covers every capital city (i.e. 8 in total) in Australia. The majority (64%) of the coworking spaces were located in the capital city centres and 20% were located within a 10km radius of the capital city centres which were often the business and commercial centres of metropolitan suburbs. The geographic locations of the coworking spaces reflect users' preferences in selecting coworking spaces. As to the age of the coworking spaces studied, they ranged between 1 and 8 years as of 2018, with the majority (67%) being founded in and after 2015. This finding was consistent with the trend of rapid growth of coworking spaces not only in Australia but also worldwide (Merkel, 2019).

Table 2 Summary of the main profiles of the *coworking spaces* studied (N=30)

Location	Est. Year	Size	Member profile*	Ownership	Operating model
City centre = 64%	2010 < = 10%	15 < = 30%	Entrepreneur = 40%	Govt-owned = 10%	CWS only = 17%
Within 10km = 20%	2011-2014 = 23%	16-50 = 23%	Freelancer = 10%	University-owned =13%	CWS & service=83%
11km – 20km = 10%	2015> =67%	51-100 = 43%	Remote worker = 10%	NGO – owned = 3%	
21km+ = 6%		100> = 3%	Digital nomad = 5%	Privately-owned = 17%	
			Local employee = 10% Student = 15% Others**= 10%	Joint venture = 57%	

Legend: CWS = coworking spaces; Size = number of active members or users
Note: Member profile* is an estimated percentage of the active members' profiles of the 30 coworking spaces studied. Others** category refers to retirees, students, and local residents who do not fall into any of the other categories.

Table 2 shows that the size (i.e. number of the active members) of coworking spaces studied varied with the majority (43%) of them having more than 50 and up to 100 active members. We found that the size corresponded well with the age of the coworking space, namely, those that were well-established often had more members than those that were relatively more recently set up.

With respect to user or member profiles, the providers we interviewed were diverse. The majority (40%) were entrepreneurs but there were also freelancers, remote and local workers, students, retirees, digital nomads and local residents. In terms of ownership, most (57%) were joint ventures, that is, partnerships between city councils, universities, established companies and/or start-ups and philanthropists. Thirteen were owned and managed by public universities and other tertiary institutions, ten percent were funded entirely by governments such as those coworking spaces in city and state libraries and only three percent were owned by NGOs. The remaining (seventeen percent) were privately owned and operated.

As far as business and operating models were concerned, all were membership-based although fee structures varied, ranging from a nominal fee or no fee to hundreds of dollars per month, depending on the type of membership and ownership. Seventeen percent of the coworking spaces we studied offered office facilities only with no or minimal services. The overwhelmingly majority (83%) of the coworking spaces offered both coworking spaces and membership services. These typically included networking events, mentoring and business-related training, business mailing address, parking, locker and shower facilities.

We found that some coworking spaces were bundled with other services such as a coffee shop, a meditation room, and a gym. It was interesting to find that nearly 30 percent of the privately-owned coworking spaces that we studied were owned and managed by female entrepreneurs. Some of them were open to women only, offering women-centric services such as child-care and salon services. Three of the coworking spaces were hotel and hostel operators which offered their guests and the general public their coworking facilities. The hostel coworking spaces were particularly appealing to international backpackers and digital nomads. Most recently, some of the coworking spaces started to offer a virtual membership option with a much lower fee to attract those living in regional and remote areas. This option provided members with access to the online coworking community and the events and activities provided by the coworking spaces.

Motivations, objectives, and outcomes – Provider's perspective

Community building and entrepreneurship

In terms of the motivations and objectives of establishing and running coworking spaces, the most striking themes from a provider's perspective are community building and entrepreneurship (see Appendix for detail). We found that the providers we interviewed shared a common agenda – creating a coworking community for members to interact with each other, creating and sharing ideas, and facilitating innovation through collaboration. One of the founders of coworking spaces told us:

> *The objective was to build an entrepreneur eco-system and seek to bring 20,000 entrepreneurs by 2021 into a membership community with 1,000 members.*

Another female owner and operator of a coworking space had one ultimate goal, that is, helping women start and build a successful business and start-up by providing a one-stop shop.

When asked about the level of success and outcomes of coworking spaces, two of the founders/owners made the following comments:

> *At our level, it is more about playing a community role than an actual money-making business, it is more about providing these start-ups with what they need and hopefully see them outgrow the space like a few did.*

> *After nearly three years' operation, our coworking spaces have helped 11 of our members set up their own businesses and 6 of them have broken even and 1 of them is very successful. We are very pleased with the results so far.*

The proceeding comments reflected the different views and motivations of providers in running coworking spaces. However, they shared a common goal of incubating and nurturing entrepreneurs through their coworking spaces.

Interestingly, for university coworking spaces, some of the participants suggested that bringing entrepreneurs and start-up workers to campuses to co-work with students and staff helped with experiential learning and idea generation and development, thus enriching students' learning experience. In some cases, we found in our interviews that students described how their social skills had been developed through the coworking spaces. University coworking spaces were also seen as an innovation hub for university entrepreneurship and research commercialisation, providing students and researchers with access to industry and insights from entrepreneurs, investors and commercialisation experts.

Motivations, objectives, and outcomes – User's perspective

Social interaction

As far as coworking space users or members were concerned, we found that people joined coworking spaces for different purposes and with different expectations. The most common reason cited by users was the social interaction among members. However, the social interaction led to different outcomes due to the different motivations of users. For some, the social interaction helped the exploration and sharing of ideas as well as developing new business and professional networks and providing needed opportunities and mentoring advice.

> *'We've been able to leverage the other people's networks since we joined the coworking space,' said one of the users.*

Prior research suggests that informal exchange and cooperation in the form of horizontal interaction with others is likely to lead to knowledge transfer because of geographical, social or cognitive proximity (Boschma, 2005). We found that the eventful aspect of coworking spaces played a key role in members' horizontal interactions and networking. For others, the social interaction helped ease the social isolation and loneliness experienced from working alone. For the remote workers we interviewed, they felt strongly about the benefits of social contact with others. One told us 'working alone at home for a while had made me almost lose my sanity and taken a toll on my health. I feel happier and less lonely since joining a coworking space'. We also found that some users felt motivated by others and were able to get more work done, compared with working at home. An increasing number of studies suggest that one of the most valuable aspects of coworking is the social interactions and social ties in the coworking community, instilling a sense of belonging (e.g. Mitev et al., 2019; Spinuzzi et al., 2019). Two of the interviewees commented:

> *It's the community that we have that makes the difference. On many occasions we have people helping each other. We have a SEO expert who is taking care of couple of other members SEO. Collaboration can mean that, if I am having a bad day, I can go for a walk with other members.*

Sharing ideas and learning from others' experiences, and co-designing and co-creation are some of the activities you see here. This aspect is particularly appealing to innovative companies and entrepreneurs (Avdikos and Merkel, 2020). In this regard, the coworking space model addresses a general concern over the recent urban

transformation that 'public spaces and their character changed as they ceased to function as facilitators for social interaction and were reserved for merely utilitarian purposes' (Mandeli, 2019, p. 2). Our findings suggest that coworking spaces can address both social-cultural needs and economic needs of the public and demonstrate a new way to serve multiple stakeholders of smart cities.

Flexibility and proximity

We found that among the users interviewed, there were two local workers who were sent by their employers to work in coworking spaces. For them, coworking spaces were a place for fresh and innovative ideas in a non-conventional entrepreneurial' environment and provided them with the flexibility in working hours with 24/7 access and proximity to home and transportation. These participants were generally happy with this workplace arrangement and appreciated the flexibility given by their companies. This finding supports the view that flexibility helps attract and retain best talents for companies (Smith et al, 2019).

Cost

Some-cost-related reasons for coworking were cited in our interviews. For example, the lower costs compared with renting an office was one of the main reasons cited by young entrepreneurs and start-ups who had little disposable income or resources. The low-cost facilities and services provided by coworking spaces also helped start-ups to get to market quicker without the hassle of office management issues and overheads according to some our interviewees. One of the users commented that the flexible leasing terms (i.e. casual rate, weekly, monthly and yearly) of coworking spaces compared with 5-10 years' lease in rental markets helped reduce capital costs.

Key challenges for providers

We found that many of the coworking spaces we studied were facing serious issues and challenges. We identified and discussed three mostly cited issues raised by the providers interviewed (see Appendix for detail).

Cost

Six out of ten space providers whom we interviewed expressed their concerns about future funding. Some of the providers indicated that they would have to close their coworking spaces when their funding dried up and if they could not find further funding. We posit that this issue may relate to the current business models of most coworking spaces. We found that most of coworking spaces we studied were not-for-profits entities. The majority of the coworking spaces except for those owned by city councils and public educational institutions, relied primarily on membership fees and corporate sponsorship through up-selling and cross-selling other services to their users as well as organizing events, trying to reach a breakeven point. Lack of support from some city councils was cited as a key issue in particular in terms of funding.

Space

Space for in coworking can be limited due to the high demand from users. Those (5 out of ten) who wanted to expand or move their coworking spaces were struggling to find affordable stock at the locations in or close to business centres and/or innovation hubs. It was reported that in Australia, coworking spaces accounted for about 5% of current city office stock and could rise to 30% by 2030 according to the current annual growth rate of 19% (Cheung, 2018). The upward trend of demand for coworking spaces could be an opportunity for advocates of smart city planning and governance to think strategically about the location, infrastructure and design of coworking spaces.

Support

Our participants were somewhat polarized in their views about the role, attitude and actions of smart city councils and urban planners with respect to coworking spaces. We found that some founders of coworking spaces were given substantial attention by their city councils. Others complained that they were rarely engaged in their city's planning process and that urban planners generally did not identify or recognize the opportunities that coworking spaces presented as a new way people can use buildings in smart cities.

User retention

Other challenges related to coworking that we found in our interviews included those associated with attracting and retaining users since most of tended to move to larger coworking spaces once they developed. The fluidity of freelance working schedules and providing parking spaces to users and their guests also made it hard for providers to meet the needs of their users and thereby retain them.

Key challenges for users

Culture fit

From the users' perspective, a vibrant community culture (e.g. shared norms, languages, and values among members) of the coworking spaces came as one of the most important issues and challenges. One of the interviews put it this way:

> *You get a culture, serendipity, community, and even with coworking in general, it's not about the facilities, it's all about the people, you want people who are of that same philosophy of sharing and helping each other.*

Distraction

Other commonly cited issues were unwanted distraction or interruption and lack of privacy in the coworking spaces. Phone calls and side conversations were the main source of such distraction. To deal with these issues, some coworking spaces developed a code of conduct and etiquette. Some members resorted to noise cancelling headphones. Superior office facilities including size of rooms and numbers of desks as well as speed of Wifi and Internet were some of the reasons that prompted people to move from one coworking space to another. A few of the users we interviewed cited the cost of membership as a main deterrent to their use of coworking spaces.

5. Discussion and Implications

This study has examined the motivations and challenges of coworking space from both providers and user perspectives. The discrepancies and similarities identified from this study have implications for researchers and practitioners in in a range of relevant fields. First, the coworking space concept and model resonates well with the concept of smart city 2.0 which emphasizes people-centric innovations and collaborative participation (Trencher, 2019). Many researchers and practitioners favour a human-centred discourse in smart city strategy and advocate for citizen and community engagement (e.g. Carrasco-Sáez et al. 2017). Our findings show that coworking spaces contribute to collaboration, openness, and community engagement, which incidentally are the key elements of smart cities 2.0 (Trencher, 2019). From urban space and environmental perspectives, coworking spaces are likely to contribute to urban mobility and sustainability. This is another crucial component of smart cities (Annunziato and Maestosi, 2018). This is because coworking spaces located in urban community areas allow people to work closer to home and reduce average commuting time and rates of carbon emission.

Second, this study addresses an important emerging scenario in today's workforce as it becomes more fluid and mobile and takes advantage of the rapid development of digital technologies. Many jobs created in the sharing economy allow workers to decide on when, where and with whom they work with. It is estimated that the majority of U.S. workers will be freelancing by 2027 (Pofeldt, 2017). In Australia, less than half of Australians are working in a permanent full-time role in 2018 and the upward trend is growing (Jericho, 2018). Casualization in the workforce has become a notable trend, which leads to a nomadic and precarious worklife (Gandini, 2015). On the other hand, the increasing demands by workers for flexibility in terms of hours with less commuting time and more work-life balance (Erden Bayazit and Bayazit, 2019) are echoed in our findings. Research suggests that coworking spaces have become a critical urban practice because these spaces provide the support to the rising number of freelancers to cope with the informality, uncertainty and risks associated with independent work (Merkel, 2019). The implication for urban planning would be the creation of more coworking spaces and reconfiguration of some of the exiting urban spaces to meet this demand. The study suggests that these trends are likely to increase the demand for coworking spaces.

Third, the findings of this study highlight the importance of social capital generated through social interaction in coworking spaces as a platform for open innovation and collaboration. From a social capital perspective, social relations, norms and identities enable actors, whether individuals, groups or even organisations, to coordinate actions in order to achieve desired outcomes (Nahapiet and Ghoshal, 1998; Tsai and Ghoshal, 1998). Relationships form an important source of social capital providing benefits of access to information, knowledge and resources (Suseno et al. 2018). Some of the outcomes of the coworking spaces studied are a clear indication of the social capital derived from relationships and exchanges in the form of capacity building, social competency and networks (see Appendix for more detail). The study of coworking spaces from a social capital perspective would be a valuable addition to smart city ecosystem research.

Fourth, from an urban economic perspective, this study shows that coworking spaces provide a collaborative environment and often a breeding ground for entrepreneurship, where entrepreneurs and microbusinesses explore and share new production opportunities often in non-hierarchical situations (Gandini, 2015). The findings indicate that coworking spaces become start-up communities driving innovation and entrepreneurship in smart cities. Entrepreneurship was one of the most salient themes in the coworking spaces as shown in our findings. With the rapid diffusion and advances of digital technologies, digital entrepreneurship becomes increasingly a driving force for the urban economy and an imperative part of smart city ecosystems. These findings will inform

urban policy makers and help them better understand and tap into this source of civic entrepreneurship derived from coworking spaces.

Fifth, from a public space perspective, the findings of this study provide insight into how public spaces can be optimally used for coworking practice. Studies suggest that high quality public spaces are likely to offer economic, social and environmental benefits to their localities and communities (e.g. Carmona, 2019). The centrality of public spaces can also bring psycho-social benefits. Given the multiplicity of public spaces whether formal or informal, coworking spaces have demonstrated their value as social public spaces that encourage social engagement and diversity and contribute to the urban social fabric. This is consistent with previous studies indicating accessibility, activity, comfort, liveliness and sociability are the common benefits of public spaces (Heffernan et al., 2014; Mehaffy et al., 2019). The coworking spaces can be used as a new form of public space and a workplace to achieve these benefits. This implies that smart city planning needs to consider innovative use of high street spaces and the role of formal or informal spaces as part of a portfolio of locations where people can work and interact.

6. Contributions, limitations and future study

This study contributes to the extant literature and practices mainly in three ways. First, it contributes to the current understanding and research of coworking spaces and their role in developing social and cultural fabrics as well as growing entrepreneurship in smart cities. The insightful findings of this study highlight the benefits generated from the coworking spaces studied and the issues and challenges they were facing. In this regard, the study will help both providers and users of coworking spaces in running and using coworking spaces in the future. Second, the study enriches smart city literature by investigating what and how coworking spaces can do in the smart city ecosystems. This novel lens sheds light on how to conceptualize smart cities, which are more about community and citizen centric than smart technologies. Third, the study and the findings inform urban policy makers and help better understand and tap into the source of civic entrepreneurship derived from coworking spaces which could become a solid base to build digital entrepreneurship for sustainable, liveable and competitive cities (Cetindamar et al., 2020).

However, like all the studies, our research has its limitations. First, from a methodological perspective, our qualitative approach does not allow the quantitative measurement of the specific impacts or effects of coworking spaces on smart city ecosystems and urban economy and city life. However, our findings provide an in-depth insight into how coworking spaces are likely to generate, both directly and indirectly, economic and socio-cultural impacts on smart cities and urban planning as well as contribute to smart city ecosystems. Future research in the form of quantitative studies could investigate the relationships between the density of coworking spaces and smart city maturity in terms of innovation, citizens' participation as well as the moderating effect of the socioeconomic characteristics of the cities in which coworking spaces operate.

Second, our study only provided a broad picture of motivations and challenges of coworking space, social relations and cultural aspect of coworking spaces should be explored at a much deeper level, which goes far beyond informal social learning (Bilandzic and Foth, 2013). For example, our findings suggest that coworking spaces help mitigate the mental and health issues of remote workers. Questions remain about the processes through which the social relations develop in coworking spaces and the role they play in not only enhancing economic performance but also fostering entrepreneurial capability building and enhancing members' mental well-being. Recent empirical research (e.g. King. 2017; Robelski et al. 2019) found that working in a coworking

space had a positive effect on mental health and reduced the loneliness and depression caused by the isolation of working from home. More research is needed in this regard.

Third, the relationship between smart cities and (digital) entrepreneurship have attracted some research interest recently (e.g. Sarma and Sunny, 2017; Kraus et al. 2019). The majority of the founders and users of the coworking spaces in the current study were entrepreneurs. Our interviews suggested that coworking spaces were a fertile ground for growing entrepreneurship. But given the limited space of our paper, we were not able to delve into the relationship further. Future research could investigate how the socio-technical network among entrepreneurs in the coworking spaces is likely to play a key role in smart cities.

Finally, at the time of submitting this paper, the global coronavirus pandemic has reached the stage where many of the providers and users interviewed in this study have had to temporarily shut down coworking spaces and resume working at home. What this study suggests is that this shock should not be allowed to result in more than a temporary pause to an important and dynamic aspect of the socio-economic systems surrounding smart cities. We posit that post-pandemic studies need to be conducted about the factors influencing the speed and scope of reconstruction of coworking spaces and the lessons learned about protecting and nurturing this vital aspect of the economic and socio-cultural fabric.

7. Concluding remarks

This paper studies the trend of coworking spaces in the context of smart cities and examines its implications in an integrative way, namely, from economic, social and cultural perspectives. By doing so, the study provides a better understanding, at a strategic level, about what role coworking spaces are likely to play in smart cities and smart city ecosystem. The findings of the study inform urban policymakers and urban planners with empirical insights into the trend of coworking spaces and the key issues and challenges they are facing, which may lead to better engagement with the trend.

Appendix – A snapshot of data display from interviews (N=34)

Main questions	Provider/ User*	Key themes & No. (%) responses	Examples (Quotes)
What are your main purposes and motivations as a provider or a user of coworking space?	**Provider** (10)	• Entrepreneurship - 10(100) • Community building - 10(100) • Collaboration – 10(100)	• *The objective was to build an entrepreneur eco-system and seek to bring 20,000 entrepreneurs by 2021 into a membership community with 1,000 members.* • *To promote and advocate for entrepreneurship, and change the culture to encourage entrepreneurship* • *To provide incubators and physical infrastructure for young entrepreneurs seeking a fashion for entrepreneurship and entrepreneurial competence* • *To facilitate collaboration, bolster motivation and provide concentrated support services*
	User (24)	• Social interaction – 22(92) • Entrepreneurship – 13(62) • Flexibility – 11(46) • Proximity – 11(46) • Services provided – 10(42)	• *Working alone at home for a while had made me almost lose my sanity and taken a toll on my health. I feel happier and less lonely since joining a coworking space.* • *Most of my coworking space members are entrepreneurs like me, from diverse background, expertise, experience and different age groups. We discuss ideas and how to make them work.* • *Flexibility in working hours means a lot to me due to family*

		• Costs – 8(33) • Lifestyle/career change – 9(38)	*commitment. The 24/7 access to this office is what I'm after.* • *This place is half-way between home and work, not merely the physical proximity but I just feel some sense of connection with the place.* • *I don't need to worry about lease, electricity bills, catering, kitchens etc. and the cost is much lower than hiring an office. I can focus on doing business and rest all taken care of by the coworking space.* • *Seeking for lifestyle change, having been in the corporate world for years, wanted to be a freelancer, having my own business.*
How do you feel about the outcomes?	**Provider** (10)	• Collaboration/community – 10(100) • New start-ups – 10(100) • business skills – 7(70) • Social competency – 3(30)	• *At our level, it is more about playing a community role than an actual money-making business, it is more about providing these start-ups with what they need and hopefully see them outgrow the space like a few did.* • *After nearly three years' operation, our coworking spaces have helped 11 of our members set up their own businesses and 6 of them have broken even and 1 of them is very successful. We are very pleased with the results so far.* • *There have been 4 VR (virtual reality) start-ups that were originated from this coworking space.* • *Intelligent students are often socially and commercially naïve. After 12 months working in the coworking space, they have improved social skills and are better leaders and managers.*
	User (24)	• Sense of community – 18(75) • Networking building – 16(67) • Capacity building – 8(33)	• *It's the community that we have makes the difference. On many occasions we have people helping each other. We have a SEO expert who is taking care of couple of other members SEO. Collaboration, if I am having a bad day I can go for a walk with other members.* • *Coworking spaces break the isolation and link you with stimulating interesting bright people with face-to-face contacts.* • *Coworking and mentors here help shape and refine my business model; this sustains me in the cash burn and long lead times and my capability development.*
What are the major issues and challenges you have?	**Provider** (10)	• Lack of funding – 6(60) • Shortage of right stock – 5(50) • Lack of support – 5(50)	• *We had council's start-up fund to open the coworking space 3 years ago, but they are not going to fund us again. We may have to close the door soon if we can't get the support.* • *I've been planning to expand given the demand but struggling to find the right stock because of location, rental price and space and time flexibility.* • *I would like to see more support for coworking spaces as it is a significant investment for local community and small businesses.*
	User (24)	• Cultural fit – 13(54) • Distraction – 9(38)	• *You get a culture, serendipity, community, and even with coworking in general, it's not about the facilities, it's all about the people, you want people who are of that same philosophy of sharing and helping each other.* • *Some people ignore the presence of others when receiving calls, talked quite loudly, sometimes I was forced to wear noise-cancelling headphone just to be able to get work done. .*

Note: We interviewed a total of 10 providers and 24 users of coworking spaces.

Fang ZHAO (PhD) is the Professor of Innovation and Strategy and Associate Dean – Research and Enterprise at Staffordshire Business School, Staffordshire University, UK. She has published over 110 research works internationally and in some of the top-tier leading journals in the study fields. Zhao's current research focuses on innovation strategy, smart cities, impact of Covid-19 on SMEs and digital transformation.
ORCID ID: 0000-0003-3718-6999

Catherine PRENTICE (PhD) is an Associate Professor of Marketing at Griffith University, Australia, and the Director of Asia Pacific Association for Gambling Studies. She has published more than 60 in Q1 or top-tier marketing and management journals within last few years. Her main research interests include service research, consumer psychology, consumer behavior, artificial intelligence, emotional intelligence, services and relationship marketing, and gambling studies.
ORCID ID: 0000-0002-7700-3889

Joseph WALLIS (PhD) is the Professor and Dean of the School of Business at the American University of Ras Al Khaimah in the United Arab Emirates. Joe's research focus is in the areas of public economics, public administration, leadership and policy reform. He has co-authored 5 books including most recently The International Handbook of Public Management Reform (Edward Elgar 2009) and Reform and Leadership in the Public Sector (Edward Elgar 2009) and has written over 90 articles in journals including Governance, World Development, Public Administration, Local Government Studies, Internet Research and Public Money and Management.
ORCID ID: 0000-0002-6584-3426

Arvind PATEL (PhD) is the Professor and Head, School of Accounting and Finance at the University of the South Pacific. A graduate of the University of South Pacific, University of New South Wales and University of Queensland in Australia, has research interest in corporate governance, auditing, financial accounting, business finance and information systems. Publications included in top tier journals in information systems, accounting and economics. Current research interest in CEO succession and stock crash risk.
ORCID ID: 0000-0002-3223-7585

Marie-France WAXIN (PhD) is the Professor of Human Resource Management at the American University of Sharjah, in the United Arab Emirates. Her research interests and publications focus on strategic and sustainable HRM in private and public organisations. She is especially interested in talent management, global HRM, diversity management, and environmental management.
ORCID ID: 0000-0002-0660-5452

Abstract. The article provides a comparative study of the possibility of entrepreneurship development based on fuzzy signals of business activity and applied elements of artificial intelligence. The principal research methods that determine the logic and practical basis of the application of fuzzy logic in entrepreneurship are highlighted. It has been determined that fuzzy modeling is effective when technological processes are too complex for analysis using generally accepted quantitative methods, or when available sources of information in the business environment are interpreted poorly, inaccurately, and indefinitely. It has been shown experimentally that fuzzy logic gives better results compared to those obtained with generally accepted algorithms for analyzing the quality of doing business. A model of a neuro-fuzzy regulator has been developed and measures for its implementation in the business environment have been proposed. A neural network model in entrepreneurial development has been formed. Studies have shown the possibility of effective use of the principles of artificial intelligence and modeling in solving problems of developing entrepreneurial potential and making business decisions under conditions of uncertainty. This ensures objective and well-grounded decision-making in solving various applied problems of business development and taking into account environmental factors. The applied tasks of supporting the adoption of entrepreneurial decisions in the conditions are formulated; uncertainty; indicating that approaches to decision-making under conditions of uncertainty based on artificial intelligence and fuzzy logic tools are universal and require appropriate careful study and adaptation to a specific applied problem in the business environment.

1. Introduction

The problem of considering intellectual activity in entrepreneurship becomes a primary one, unlike the approach of designing traditional artificial intelligence systems from the 'bottom-up' principle based on "rigid models" of information management systems. This approach requires deviation from the concept of "regulatory management models". The basis of a new subject-oriented approach to the entrepreneurship development is research aimed at developing methods based on the selection of psychological features of managerial activity that can be introduced into the model of artificial intelligence (Axelrod, (1997). This position is based on the position of cognitive psychology and attempt to formalize actions typical for the entrepreneur in making commercial decisions and system development. These provisions form the relevance of this study.

2. Literature Survey

In modern scientific literature, it is advisable to single out groups of researchers on the development of entrepreneurship based on methods of fuzzy logic and applied elements of artificial intelligence.

1) *Constructive and instructive presentation of the development process in entrepreneurship*. The traditional developmental command system used is changed to the presentation of educational material in the form of constructor for knowledge building by the "pupil" (Petruzzi, Dada (2002); Snow et. al. (2017). The author's intention is to provide instructions for using the "knowledge constructor" within a particular subject area. As (Walker, (2010); Whitehead and Choate (1994) points out in the model of artificial intelligence development - it is "electronic" technology, wherein the new education system based on artificial intelligence has decision-making power while working with the "designer knowledge".

2) *Intellectual "building pedagogy"*. Computer information development in entrepreneurship must have powerful intellectual tools for organizing the process of integrated education (see Bostrom & Yudkowsky (2011); Dejoux, Léon (2018); Kornienko et al. (2015). The distinctive characteristics of such tools are the requirement of a non-linear process of ensuring the development of business activity.

3) The applied issues of artificial intelligence in business are considered in the works (Bostrom & Yudkowsky (2011), Weiß and Sen (1996); Kwilinski & Kuzior (2020)). The authors highlight the problem that entrepreneurship today cannot be based on discrete data. It is necessary not only to systematize information using the latest software advances but also to provide dynamic observation in the business environment, as well as to set up an algorithm for automating decisions to reduce costs in an environment of strong competition and incomplete information.

4) In the works (Drobyazko S., et al. (2019); Drobyazko S., Barwińska-Małajowicz A., et al. (2019); Olsher (2015)) it is indicated that, unlike a fuzzy set, which expresses the inaccuracy in the assessment of a certain attribute, the measure of opportunity describes uncertainty, the incompleteness of information related to the appearance of a particular event. In fact, this is a way of quantitative description (representing the meaning) of expert judgments, which is a generalization of interval analysis and the theory of errors. Currently, the measure of opportunity and its dual measure of necessity act as the main means of modeling uncertainty in entrepreneurial activity.

5) In scientific works (Ceruttia et al. (2019); Mirjalili (2019)), the artificial intelligence elements design methodology based on systematic research and empirical assessment of processes in different socio-economic systems, algorithmic variations, and choice of solutions in individual activities are presented in detail.

3. Methods

In the current study, the methodology will be considered as a set of successive actions of practical implementation of certain research processes, their procedures and operations, which achieve the solution of the research goal. In the article, the methodology forms the structure of the study, it determines the set of relevant patterns, principles, and techniques used in the disclosure of topics and the formation of scientific novelty and conclusions. The methodological basis of the research was formed by:

1) a method of formalizing processes and logical presentation of results. In a formalized scheme, all characteristics of the complex process of functioning of the system as a whole and of its individual elements are formally determined. According to the methodology, it is necessary to formally determine the parameters of processes and states, all dependencies between the characteristics and parameters of the system as a whole and its individual elements, taking into account those factors that are taken into account during formalization. The formalized scheme contains an exact analytical formulation of the task of studying the processes of business development, the set of all initial data, known parameters of the process and initial conditions.

2) The method of variants of the structure of goals. Within the framework of this methodology, the concept of correspondence between two scales of development of complex systems - a spatial scale and a temporal one relative to entrepreneurial activity is distinguished. The principle of allocation of components at the top level of the structure of goals for solving new, unexplored problems is highlighted. The "pyramid" principle, which helps to understand the branches of the goal tree, characterizes the volume of the goal area, and experience has shown that consistent movement along the edges of the "pyramid" with a return to the highest level in the already structured branches, taking into account the new vision of the development of entrepreneurial potential helps to reveal the goal area.

3) The method of structuring goals in a fuzzy representation of business processes. For the effective organization of entrepreneurial activity, an information system is needed that allows, using computer technology and new information technologies, effectively organizing the work. In the factorial representation of the decision-making information system, these components as labor resources, material and technical support, and other objects of entrepreneurial activity are distinguished

4. Results

The purpose of the current study is to form organizational principles and methodological approaches to business development based on the components of artificial intelligence and fuzzy regulators in business. The purpose of the study is determined by the need to introduce new approaches to entrepreneurship, which can accelerate development and provide quality modeling of areas of activation.

The basic principle of building a fuzzy regulator in the entrepreneurship education is based on the experience formalization of the intelligent operator which manages a dynamic object by means of the linguistic rules "if ... then" (Galbraith (2014).

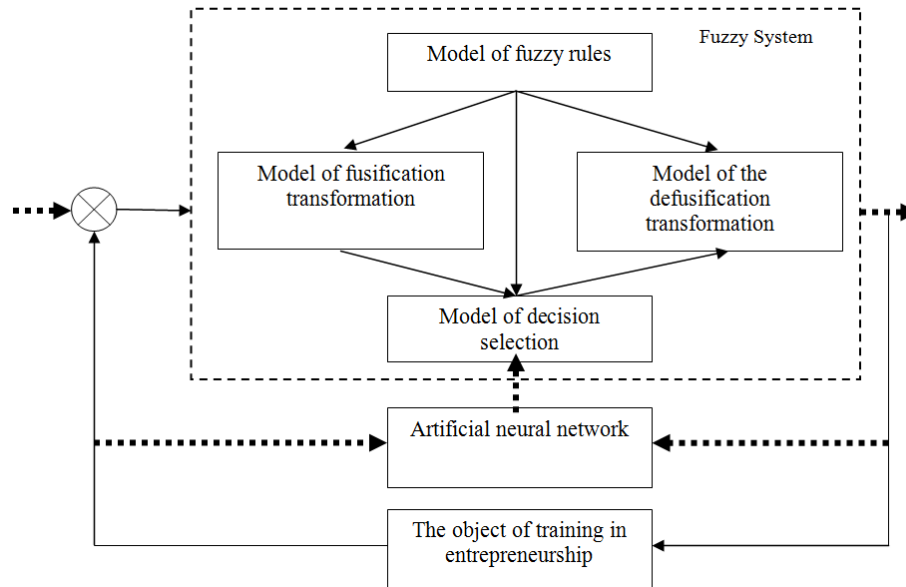
The decision-making module processes fuzzy information based on a set of linguistic rules contained in it - heuristics, which are defined by the entrepreneur in the form of a language similar to the natural language of the type "If *P*, then *C*" (González et. al. (2015). Each linguistic rule contains one or more conditions for its application and appropriate action to this condition (Fig. 1).


Figure 1. Architecture of fuzzy regulator in entrepreneurship development
Source: the authors

Note that an additional parameter *I* may be introduced by the expert for each fuzzy rule W_i characterizes the significance of the rule (Choe, H. & Jordan, J.B. (1992)). Then each rule is formalized in fuzzy logic by the expert's opinion which contribution to the overall score makes a fuzzy value, and the decision selection module calculates the indicated weights (Fig. 1). Note that each rule of the system analyzes only one metric. In case when there is more than one indicator, the set of input fuzzy concepts in the rule parcel is combined by the fuzzy "*I*" operation (Luckin (2017); Seifollahi et al. (2012):

$$\text{«if } P_i \text{ and } P_j \text{ and ... then } C_t \qquad (1)$$

where:
P – parameter of the fuzzy input concept;
C – parameter of the fuzzy output concept;
i – input number defining the index X_i which is defined the fuzzy concepts and linguistic rule;
j - number of fuzzy concept defined for input X_j.

When a logical condition consists of a set of fuzzy input parameters *P* combined by a fuzzy conjunction operation "*and*". Each input fuzzy concept is implemented by a fusificator of the fuzzy controller and defined at one of the fuzzy controller inputs (the input number is identified by the label index). Generalizing the result of performing fuzzy logical transformation into a single clear value at the output of the controller is performed by the defusificator (Skute (2019). Given above about the additional parameters *W*, defusificator integrates various parameters "twos" - "C_i and W_i.

Combination of the benefits of entrepreneurial development and artificial intelligence is possible through the synthesis of neuro-fuzzy systems, based on the principle of functional equivalence of architecture (Maderer (2016); Powell (1992)). The essence of the principle is interchangeable use of benefits of different classes of the architecture.

Below, we propose an algorithm for entrepreneurship development based on artificial intelligence. Activity of F_j of each i-th output element of the business development system depends on the input vector x as follows:

$$F_j(\bar{x}) = \omega_{i0} + \sum_{i=1}^{L} v_{ij} \phi_i(\bar{x})$$

(2)

where:
ω_{j0} - threshold value of the j-th output;
v_{ij} - weight connecting i-th hidden element with j-th output;
ϕ_i - nonlinear transformation performed by a hidden element.

The nonlinear transformation is performed by the number L of the radially symmetric basis functions, pre-correlating inputs with the eigenvalues of the center and deviation, i.e. $\phi_i(\bar{x}) = \phi_i(\|x - c_i\| / d_i)$, where $c_i \in \Re^n$ is the center of the basis function ϕ_i a d_j is deviation or scaling factor for radius $\|x - c_i\|$, a $\| \ \|$ - usually Euclid's norm in $\Re^n$. The Gaussian form $\phi_i(r) = exp(-r^2/2)$ is most often used as a function ϕ, which gives the finality of nonlinear transformation. In general, the task of development is to minimize the function of the network error E, which expresses the standard deviation of the network outputs from the required on a given (usually fixed) set of training pairs "input-output" during training:

$$E = \frac{1}{2KM} \sum_{i=1}^{K} \sum_{j=1}^{M} (t_j^i - o_j^i)$$

(3)

where:
K – number of training pairs;
$t^i_{\ j}$ – the target value of the output neuron when i-th input image is presented to the input;
o^i_j - real output of the output neuron when i-th input image is presented to the input; The network outputs are limited by the interval (-1,1), and the target values acquire only two possible values $t^i_j \in \{-1;1\}$.

As it is known, the radial elements with Gaussians have one very important property - action locality – the function influence can be neglected ϕ_i at a distance of more than $2d_i$ from the center c_i. This property makes it possible to evaluate the efficiency of each element independently of the others, thus to independently select the elements in the next generation. It significantly accelerates convergence of the algorithm. The following function is used to evaluate efficiency of the individual element ϕ_j, which coincides with the defusification function by virtue of the principle of functional equivalence:

$$e_j = \frac{\sum\limits_{x_k \in r} \phi_j(\overline{x_k})}{\sum\limits_{k=1}^{L} \phi_j(\overline{x_j})}$$

(4)

where:

e_j - efficiency value of *j-th* element;

$\phi_j(\overline{x_j})$ - output value of *j*-th element when the image is submitted to the input;

$\overline{x_k}$ - images of the instructive class sample *r*, the sum of the outputs is maximum for them.

This function determines how much this element ϕ_j distinguishes the class *r* from the training images of all other classes. The initial rule strategy is to maximize the values e_j for all hidden network elements. The first stage of the calculating efficiency provides finding of the values which this neuron picks up in each class. Then the maximum value is selected among these quantities and correlated with the total activity of the radial element. The great advantage of this function is the following - it does not require knowledge of the output weights (Kathirvel et. al., 2019). Thus, it is possible to improve the centers and deflections of the elements without developing the input parameters in the enterprise, which greatly reduces the average time of one iteration.

The above function (4), unfortunately, does not meet these requirements. Its use in the input space implies minimums which the element seeks to occupy. As much as possible, the duplication degree of two radial elements ϕ_i and ϕ_j is expressed as the orthogonality of the vectors of the normalized activities of these elements on the initial sample images:

$$R_{ij} = \frac{\sum\limits_{k=1}^{K} \phi_i(\overline{x_k})\phi_j(\overline{x_k})}{\sqrt{\sum\limits_{k=1}^{K} \phi_i^2(\overline{x_k})\phi_j^2(\overline{x_k})}}$$

(5)

Note that if the radial elements aren't intersected, then R_{ij} equals to zero (i equals to one if work of neurons is completely identical). Accurately calculation of the orthogonality activities for all pairs of elements is quite a time-consuming procedure. Therefore, it's needed a compromise solution requiring much smaller calculations: we will only use the maximum activity condition for each of the radial elements ($p \ll K$) to determine excessively competing elements; *p* often equals to 1 or 2, and others are equal to zero. If the result is not zero, then elements ϕ_i and ϕ_j are considered as duplicates.

The given block of formulas defines a methodical approach concerning introduction of a neuro-fuzzy regulator in business activity. At the same time, there is a need to determine the basic set of risks and threats to the development of business stabilization of a particular business entity in order to select a clear neural regulator or their composition for further use and business effects.

The main distinguishing features of an adaptive entrepreneurial development model are the presence of subjective expert's knowledge (represented by a set of linguistic rules) and development procedures based on objective data from the subject area (see Weiß and Sen, 1996). Note that the development procedure for the model of adaptive

neuro-fuzzy controller allows to automate the selection process of internal parameters of the controller, depending on the "quality" of external parameters (Fig. 2).
Figure 2. Architecture of the adaptive neuro-fuzzy regulator development in entrepreneurship
Source: the authors

A logical structure of entrepreneurial development is formed at the first stage, which establishes a set of linguistic rules by an expert. Describing a specific set of rules, the expert thereby sets out a strategy to achieve the goal of the system (for example, for a management task, the goal may be successful management of entrepreneurial development) (Metelenko et. al., 2019).

At the second stage the designed system of adaptive development is considered as an adaptive network with a fixed structure and corresponding set of changing parameters, its values can be changed by the genetic algorithm of parametric development of neural networks based on the used real assessments of the work quality by the algorithm.

From a functional point of view, the genetic algorithm (GA) is an active "black box". GA uses an analogue of a biological individual and its natural genotype for implementing a genetic mechanism of the useful information accumulation and search. If a priori data from the external environment are absent, GA searches for the highest evaluated solutions, based only on the estimates of the solutions previously offered by them (Olsher, 2015).

Distinctive properties of the solution (individuals) are stored in a special data set – the artificial chromosome which creates the genotype of the individual. In this model, which optimizes the process of management, the quality criterion – K is used as the criterion for solving the optimization problem, the set of Pj values, ie the tuning parameters is used as an artificial intelligence individual. The values of Pj are encoded in the chromosome by the distinguishing properties of the solution of the problem and they are proposed to be considered as a set, which we denote as P. Artificial intelligence initialized by a specific set of tunable parameters values P_j, set of P_j, parameter values P is the coded in chromosome distinctive properties of the solution

For the case of a fuzzy controller, the genetic algorithm can be used to calculate the values of W_i of linguistic rules based on statistics about results of the common activity of the fuzzy controller and the object of the entrepreneurial development. Obviously, the optimal values of the weights W_i will be the values which characterize the minimal difference between the estimates of the artificial intelligence work and the real estimates.

Then the objective function is calculated based on the Euclid distance between the vector formed by the set of estimates provided by the development system and the vector consisting of real estimates by the following formula:

$$\overline{Y} = \frac{1}{D} \sqrt{\sum_{i=1}^{D} (Y^d - R^d)}$$

(6)

$\overline{Y}$ – target function;
Y^d – estimate predicted by the development system for the solution d;
R^d – real estimate for the solution d;
d – decision number;
D – number determining the number of solutions (number of GA attempts to find the optimal solution).

Thus, the vector of weights significance W_i serves as the set of optimizable parameters. The specific set of values W_i determines some solution of the optimization problem (individual) stored in the GA chromosome. The automatic management system is formed from the object of development (OS) and the adaptive neuro-fuzzy network. The current status of the OS S_i enters the input at each moment of time t_i. Based on it the artificial intelligence forms the action F_i, which enters the OS and thereby close the feedback. The goal of the neuro-fuzzy process is to bring the OS from its current status S_i to the target state S_{tar} through the management action F_i. The management carried out by a neuro-fuzzy network depends on its logical structure, as well as the values taken by the many customizable parameters presented in it. If the logical structure of the neuro-fuzzy network can be completely determined based on the entrepreneur's knowledge of the OS management, then the values of the tunable parameters are only identified approximately (Talatahari et. al., 2012).

As a result, opportunity of improvement the work of the artificial intelligence model is arisen by finding a set of parameters values of the neuro-fuzzy network, quality optimizing some criterion – K management of OS.

Calculation of the quality assessment of the neuro-fuzzy network is realized by the block calculator of the development criterion. This calculator has ability to initiate a sequence from N tests of the work of the neuro-fuzzy network. At the beginning of each test, an OS is initialized by some initial status S^0_k, after the functioning of an OS is simulated under artificial intelligence, during this process it tries to bring the system from its initial status S^0_k to the target S_{tar}. The development system monitors the status of OS S^i_k at each moment of discrete time t_i. Based on these observations, the development system calculates the assessment of the work quality of the neuro-fuzzy network in the test (taking into account success, speed and accuracy of aspirations S^i_k to S_{tar}). The criterion value K_j, corresponded to the tested parameter set P_j in the neuro-fuzzy network, is calculated as an integral estimate with relatively to the estimates calculated in the individual tests.

The process of optimization of the adaptive neuro-fuzzy network is divided into cycles, each of them evaluates one variant of the optimization problem solution defined by some set of parameter values P_j. The following actions are performed in each cycle: GA issues another estimated set of parameters values P_j which initiated the artificial intelligence block.

The search process implemented by GA tends to find and make better solutions in optimization cycles. Thus, after a certain number of optimization cycles, an optimal set of values P_{opt} having maximized K can be obtained. In this case, management carried out by a set of values P_{opt} initialized, will be optimal in the sense of the entered criterion of quality management K.

Studies in the development of real models have shown that the second (stochastic) method is more acceptable for real objects. The formulas for calculating the criterion *K* can be determined in the case of an arbitrary OS. It is necessary: to highlight a subset of the initial status variables in a set of OS status variables; to attribute weights of relative importance to them; to express the goal of management over the value of OS status variables and to introduce an algorithm for setting initial OS statuses in tests by any of the above methods (March, 1991).

The chromosome is a bit-bit grid broken down into sections. Each section has a certain parameter, such as the weight of the linguistic rule W_i. In general, the chromosome encodes the initial set of weights, i.e. parameters of the tunable neuro-fuzzy system. It is obviously that each parameter W_i corresponds to several bits of the chromosome for the numerical representation of this parameter and, thus, the search range for the parameter representation. Different combinations of the parameter values cannot exceed the range. In the general case, the order of the presented parameters, their number and the bit of each parameter may vary at the initial chromosome task, but in the future, the accepted representation of the encoding information in the form of a chromosome remains unchanged (De Lange, 2015). Considering the accepted method of encoding individual parameters, the complete chromosomal set is a sequence obtained by combination of bit representations of some number *n* of the tunable parameters, as shown in Fig. 3.
Figure 3. Bit sequence of encoding by the chromosome parameters of the neuro-fuzzy entrepreneurial development (Mallonas, 1994)

The GA procedure operates with multiple chromosomes (population of individuals), modeling the "natural tools" of evolution: competition of individuals, reproduction of individuals with the inheritance of the genes of the parents in the descendants, gene mutation.

The essence of the genetic search procedure for the adaptive neuro-fuzzy regulator in business education proposed in the paper is as follows.

1° To generate randomly the initial plural population of *n* chromosomes.
2° To evaluate each chromosome of the population using a target function (optimization criterion). The evaluation of each chromosome is done by decoding the neuro-fuzzy controller into a set of parameters values, initialization of the neuro-fuzzy controller by the obtained set of parameters, conducting tests according to the algorithm of entrepreneurial development and calculating the value of the criterion K_j which is estimation of the chromosome.
3° To break the population of individuals into random pairs and to generate two descendants from each pair by the use of crossover operators with probability p_c and mutations with probability p_m. Dividing population into random pairs is implemented by performing *n* random paired permutations in the list of population's individuals and further merging into pairs of neighbors on the list, for example (*1-2, 3-4, ..., n - l - m*). Generation of the descendants' pair is carried out in two stages. The first stage determines the occurrence of a random event relative to the crossover, based on the probability p_c.

The crossover and mutation operators work with the chromosomes as a homogeneous bit sequence, without isolating fragments representing individual parameters of the neuro-fuzzy system. The crossover operator has two parental chromosomes at the input and generates two descendants' chromosomes constructed from the genes (bits) of the parental chromosomes. Figure 4 explains the content of a "simple one-point crossover".

4° To evaluate received n descendants using the target function. The assessment is made in a similar manner to the method described in item 2.

5° To choose n the best individuals for the next generation from joint variety of the sizes $2n$ of parents and descendants.
Figure 4. Model of a one-point crossover in the artificial intelligence system

The "softness" of selection is needed to prevent premature convergence of the algorithm to a solution in which the global optimum can be missed due to the small number of GA iterations. The 'roulette' mechanism does not guarantee that the best decision in the population will be preserved in the next generation (Schuhmacher & Kuester, 2012).

6 ° The end of the procedure in case of its completion, otherwise transition to item 3. The fact of the achieving an estimate of the best chromosome in the current population is considered as the main condition of completion, as well as the condition of stopping the algorithm for exceeding the specified number of iterations N_{max} of the genetic algorithm is taking into account.

As a result, the novelty of the study is the neural network model in entrepreneurial development through which the business entity can model variations in the development of entrepreneurial initiatives, identify strengths and weaknesses of new projects, and compare alternative business options in terms of profitability and costs.

5. Discussion

Prospective recommendations in the field of entrepreneurship and artificial intelligence can be formed in the context of the model synthesis of the neuro-fuzzy execution of the functional equivalence procedure of the basic elements of fuzzy networks and artificial neural networks. This approach will help to formulate the task of the model synthesis of the adaptive neuro-fuzzy regulator. Such model will allow to transform the neural network development algorithm into a fuzzy system in the future and, thus, to use neural network optimization algorithms for fuzzy systems in business education. The main distinguishing features of the adaptive model are the presence of subjective expert's knowledge and development procedures based on objective data from the subject area.

Conclusions

It is determined that the fuzzy model of the regulator integrates the capabilities of the fuzzy system to incorporate knowledge in the form of linguistic rules set by the entrepreneur in the process of beginning development. The optimization process leads to the need to take into account the interplay of not only linguistic rules on the efficiency of the fuzzy controller, but also the interplay of fuzzy parameters within one rule. The variant model of the neuro-fuzzy controller proposed in the paper allows integration of the fuzzy system capability to incorporate entrepreneur knowledge in the form of linguistic rules, as well as possibility of neural networks to develop.

A set of rules for the use of the fuzzy choice was formed, which will allow considering the result of the fuzzy choice as an investment of the fuzzy factor in the criterion space as a set of fuzzy one-dimensional criteria that characterize the state of the entrepreneurial system at certain intervals. A methodological approach to fuzzy choice has been developed, in which the choice function is formed from the choice functions for individual fuzzy relations, and the choice can occur in several stages. The mechanism of sequential fuzzy choice and the mechanism of parallel fuzzy choice are formally defined.

Abstract. The study aims to scrutinize the level of administrative empowerment involving its dimensions (delegating powers/devolution of authorities, independence, learning, and training) on institutional performance (commitment to quality standards, achieving the goals, and staff performance) of Al-Ahliyya Amman University (AAU). The researchers applied the descriptive-analytical method by developing a questionnaire that was distributed among a simple random sample consisting of (200) members, and the data were analyzed, and the assumptions were tested using the statistical program (SPSS v20). The findings of the study revealed that there was a statistically significant impact of the level of administrative empowerment including its combined dimensions on the institutional performance at AAU. Furthermore, there was a statistically significant impact of the level of administrative empowerment involving its combined dimensions on the commitment to quality standards at AAU. The researchers recommend adopting a strategy that achieves the implementation of modern management concepts at AAU such as career empowerment, Total Quality Management (TQM), and teamwork, as well as focusing on the qualification of AAU staff. Such training will help workers practice career empowerment through the implementation of specific action plans for developmental purposes, the development of annual training plans, the use of effective means such as lectures, and motivating employees to participate in training courses and activities.

Keywords: administrative empowerment; devolution of authorities; job satisfaction; decentralization; institutional performance; teamwork

1. Introduction

Administrative empowerment is a contemporary concept that seeks to raise and develop individuals' capacities and skills to solve their managerial problems and offer them opportunities to initiate and challenge; by encouraging them to shoulder responsibilities for the decision-making, cooperation, and participation to achieve the desired goals. Moreover, administrative empowerment is considered an effective strategy that enhances managers' performance, as they have a high level of capacities and skills in addition to job satisfaction towards their organizations and careers. This will be maintained by providing them with full freedom at work to think and act independently under the umbrella of administrative decentralization methodology (Khalayleh, Masa'deh &Al-Lozi, 2017). Administrative empowerment is based on building-up trust between the workers and their leadership and encouraging them to participate in the decision-making process, in addition to breaking administrative and organizational barriers between the leadership and the staff. It also incorporates offering workers the freedom to act and enhances their participation in decision-making, and thus it guarantees the quality of the leaders' performance in administrative implementation and creativity at the same time. The typical result of administrative empowerment is represented in helping the administrative leadership obtain the uttermost benefit from the available human and material resources in their institutions to accomplish the desired goals of their organization and thus the outcome will be a higher level of job satisfaction. (Al-Omari et al, 2020). Since organizations are seeking to keep pace with the trend towards growth and development, they have to respond to the requirements for applying the principles of open management, decentralization, the delegation of powers/ devolution of authorities besides participating in decision-making to enhance the level of knowledge, skill, and administrative professionalism and improve institutional performance. Effective performance is a part and parcel of the enterprise system and is one of the most important programs that aim to achieve the goals of the organization, and it is also very essential to improve and enhance performance and upgrade the level of workers. (Uddin, 2017). Decentralization is a modern reform process that is embraced by many sectors with different types of business, and modern companies have adopted a decentralized hierarchy, which is expected to raise the level of creativity among employees. However, the tendency towards decentralization must be properly applied, restrictive, and a limited process. Excessive decentralization may create a state of chaos in the company (Thomas & Priyanka, 2014). In light of the importance of institutional performance and the role of administrative empowerment in achieving necessary skills to improve employees' performance and the devolution of authorities that enable them to solve problems practically and efficiently, this study seeks to identify the level of administrative empowerment in institutions and detect its impact on institutional performance at the AAU. The gap in previous researches is the impact of administrative empowerment on institutional performance. Administrative empowerment concerns raising and developing individuals' capacities and skills. Moreover, it can be employed by applying modern management concepts such as career empowerment, (TQM) and teamwork, as well as focusing on the staff qualification. One of the biggest challenges that most of the firm's face is the centralization of powers which delay and slowing down organizations from achieving its tasks, activities, and interest. Administrative empowerment is a very promising area for most of the organization. Thus, to fill this gap, this research aims to determine the impact of administrative empowerment including its dimensions (delegating powers/devolution of authorities, independence, learning, and training) on institutional performance in the AAU into the Jordanian context.

2. Problem and Questions of the Study

Empowering workers brings many benefits to the organization as it works to develop managers 'way of thinking, develop their creative capabilities, and allow more time for them to focus on strategic matters, develop visions, formulate long-term mission and goals, and draw long-term plans (Al-Maghribi, 2001). To the essential impact of applying the strategy of empowering workers to the success of the organization, because empowerment is an inevitable response to achieving the comprehensive quality requirements. The researchers believe that one of the phenomena of the administrative problems is the tendency of academic leaders in universities to concentrate power and not delegate it to their subordinates. Which causes a low spirit of enthusiasm and satisfaction among workers and thus, contributes to weakening the institutional performance. The phenomenon of centralization of powers or authorities among senior officials is considered one of the most important administrative problems facing institutions, as it leads to the sluggish implementation of organizations' tasks and activities. This phenomenon also entails paying more attention and preoccupation to routine work rather than the important administrative work involving basic tasks of the departments and the leadership such as planning, development, monitoring the progress of the institution, and policymaking. The administrative empowerment process is an inevitable action that is performed to maintain smooth and continuous implementation of various procedures and work practices in administrative units. Also, administrative empowerment allows senior management to make better use of its time rather than being engaged in routine work, and it also contributes effectively to the process of developing and improving the decision-making styles. The problem of the study lies in the fact that many institutions in Jordan are still so dependent on centralization, as they do not enable workers to perform administrative tasks, and not allowed to take part in decision-making despite the recommendations of many studies such as (Radhy, 2010, Al-Ajrafi, 2017, Al-Suhimat, 2016) to focus on the importance of administrative empowerment in improving creativity, achieving job satisfaction, and organizational creativeness in various institutions. The research problem is mainly focused on the phenomenon of the inclination of administrative leadership in institutions towards the centralization of their authorities rather than delegating power to their subordinates. Such tendency has some negative effects facing service institutions, and this is reflected in employees' enthusiasm to work sincerely and reduces the degree of job satisfaction among workers, and thus, leading to poor institutional performance. This study has been conducted to detect the degree of administrative empowerment of managers involving (delegating powers/devolution of authorities, independence, learning, and training) at the AAU. Moreover, the researchers aim to address the level of institutional performance including (Commitment to quality standards, achieving the goals, and staff performance) at the AAU. The study also aims to determine if there is an impact of administrative empowerment on institutional performance at AAU and identify if there are any significant statistical differences in the level of administrative empowerment on institutional performance AAU that could be attributed to demographic characteristics.

3. Significance of the study

The significance of the study is attributed to the importance of improving the level of performance in AAU through ascertaining the level of administrative empowerment and explaining its impact on the competency of institutional performance.

4. Objectives of the study

This study aims to detect the importance of administrative empowerment and its impact on the institutional performance of the AAU, including the following targets:

1- Identify the reality of the level of administrative empowerment and institutional performance at AAU.

2- Reaching results and recommendations that contribute to achieving and distinguishing institutional performance by improving the level of administrative empowerment

3- Analyzing the impact of administrative empowerment on institutional performance at the AAU.

5. Procedural Definitions of the study terminology

Administrative empowerment is defined as "the process of offering individuals greater authority to experience monitoring, shoulder responsibility, and invest their capacities, by motivating and encouraging them to make decisions and take personal responsibility to develop the way through which they perform their work and tasks by devolution of authorities to empower them in taking decisions at the lowest level (Al-Abdullah, 2018:16). Administrative empowerment is also represented in "Paying more attention to workers by expanding their authorities or influence, enriching the amount of information given to them, increasing opportunities given to them to take initiatives and make decisions and confront problems that impede their performance" (Al-Ajrafi, 2017: 155). Administrative empowerment is also known as "The relationship between risk-taking, daring and flexibility and the ability to persuade others, as well as using the scientific methodology to think and solve problems and this is one of the most creative behaviors of workers" (Radhi, 2010: 67).

Decentralization is defined as "The delegation of authorities/devolution of authorities for the lowest levels of positions, and it reflects the extent of the management's ability to distribute tasks within its authorities among its sub-ordinate personnel or other multiple entities across various administrative levels in a way that allows them to participate in the decision-making process, and to manage administrative issues of the organization" (Radhi, 2010, p. 15). Institutional performance is defined as "the extent to which the organization's goals are pursued and achieved" (Qalbo, 2015: 35). Accordingly, researchers find that the most important axes of the administrative empowerment process are the following: education, training and delegation of powers.

6. Previous Studies/Literature

A study conducted by (Al-Abdullah (2018: 16), aimed at exploring the dimensions of administrative empowerment and determine the degree of its implementation from the perspective of workers at HP in Saudi Arabia. The findings showed that there was a statistically significant effect from the perspective of HP employees in Saudi Arabia, relating to the "impact of devolution of authorities", "teamwork", "training" and "motivation" as the dimensions of empowering workers in its influence on improving professional performance. The researcher recommended that the company should strengthen communication ties among administrative various levels and maintain dependence on teamwork to accomplish required job tasks.

Al-Ajrafi's study (2017) aimed to identify the status of administrative empowerment of heads of faculty departments in Shaqra'a University in Dwami and its correlation with achieving job satisfaction. The findings revealed that there was a high and significant correlation between administrative empowerment and job satisfaction, and the researcher recommended give more attention to developing the capacities of heads of administrative departments to empower them to perform their job tasks successfully.

Al-Madadha (2016) made a study to discuss the effect of (empowerment of leadership, the environment of empowerment and psychological empowerment) and their impact on the creative and professional performance of employees. The researcher focused on detecting if there was any possible correlation between the integrative approach of empowerment and the creative performance of employees. The results indicated that there was a positive impact of the empowerment of leadership on the empowerment environment and psychological empowerment. Similarly, the empowerment environment has had a positive effect on psychological empowerment, and also the psychological empowerment has a positive impact on the creative performance, besides the importance of empowerment and its effects on the creative performance of employees.

Jiang, Flores, Leelawong, and Manz (2016) aimed to study the effect of the relationship between empowerment and team performance by focusing on the mechanisms of knowledge interchange and conflict within the group. The results showed that team empowerment can increase knowledge interchange and conflict within teams or groups work and that knowledge sharing facilitates team performance, while conflicts within a group weaken the public. (Al-Suhimat, 2016) aimed to analyze the impact of administrative empowerment on organizational creativity of workers in Mu'tah University, Jordan The researcher advised that the University of Mu'tah should pay attention to the concept of administrative empowerment and take policies and procedures that raise the level of awareness of this concept among employees by holding training courses for this purpose.

Abu Ruman, (2016) conducted a study to identify the impact of administrative empowerment on improving workers' creativity at Jordan Private Administration Institute (JPAI). The findings of the study indicated that there was a statistically significant impact of administrative empowerment (devolution of authorities, staff training, effective communication, and employees' motivation) on creativity improvement among employees in JPAI. The study recommended applying modern managerial concepts such as activating the principle of participation, working in groups, forming a team, and taking administrative decisions.

Shaqoura (2015), exploring the degree of the attention and interest given by secondary schools' principals in Gaza governorates to the requirements of administrative empowerment and their correlation with their achievement culture. The study concluded that the administrative requirements came in the highest ranks, followed by the organizational requirements and finally the logistic requirements. There were no statistically significant differences detected for the requirements of administrative empowerment that can be attributed to the variables of (gender, years of service/experience, and the educational qualification).

Aseeri and Al-Dhamen (2015) conducted a study aimed to explore the impact of job empowerment on improving their performance. The study revealed that there was a statistically significant effect of the dimensions of job empowerment (independence and freedom to act, sharing information, and management support) on improving employees' performance and the impact of the degree of performance improvement as a whole through the degree of job empowerment.

A study of Al-Qurashi (2014), aimed to identify the effect of empowering workers for the sake of improving job performance in health institutions in Taif. The results indicated that there were no statistically significant differences between the opinions of workers in health institutions in Taif, Saudi Arabia (including the physician, the nursing staff, and other workers) on the dimensions of (empowering employees, clarity of the purpose, ethics, recognition, and appreciation, teamwork, and participation). The findings also showed that there were no statistically significant differences from the perspective of workers in health institutions in the city of Ta'if relating to (clarity of purpose, participation, ethics, recognition, appreciation, and teamwork) as these include the dimensions of empowering workers and have an impact on improving their level of job performance.

Al-Ta'ani and Al-Suwai'i (2013) conducted a study aimed to identify administrative empowerment and its relationship to job satisfaction among principals of public schools in Dammam Governorate, Saudi Arabia. The findings indicated that there was a strong positive correlation between the degree of administrative empowerment and the degree of job satisfaction. The researchers recommended that job satisfaction should be given priority among other issues and receive more attention from the AAU of Education and give them more material and moral incentives for workers to maintain their job satisfaction.

Chen (2011) tried to explore the relationship between empowerment and employees' performance in the Malaysian auto industry and the effect of empowerment on employees' performance to determine which of the four empowerment dimensions had the greatest impact on employees' performance. Four dimensions were considered independent variables including (empowerment, competency, self-determination, and influence) whereas employee performance was the dependent variable. The results indicated that workers in the automotive industry think that empowerment strongly affects their performance and that there is a significant correlation between the dimensions of empowerment and employees' performance. They feel that their performance will greatly improve when they are independent, free, and have opportunities to influence the decision-making process in their work or their organizations.

Radhi (2010) study aimed to determine the relationship between administrative empowerment represented by its dimensions (delegation/devolution of authorities, teamwork, training, effective communication, and motivation) and the creativity of workers that includes (risk-taking, flexibility, persuasion, and scientific methodology in thinking and problem solving). The study revealed that there was a relationship between administrative empowerment and employees' creativity in addition to the existence of partial support for administrative empowerment correlation with most variables relating to employees' creativity. The researcher recommended that strategic leadership in the college should continue its policy in giving more attention to administrative empowerment to increase the level of workers' creativity in the areas where the response to administrative empowerment variables was reported.

Arieqat (2009) argues that empowerment is a transfer of responsibility and authority, and an invitation for workers to share the knowledge and information provided by the organization through its database, in problem analysis, and in decision-making, which lies within the decision-making authority. So, the subordinate will be responsible for the quality of what he/she decides to do, or what type of job to perform which leads to transferring the authority relatively, from the boss to the sub-ordinate employee.

Carter (2009) conducted a study to detect the relationship between organizations' behavior and the degree of employees' empowerment. The findings of the study showed that most workers were more productive if they were empowered by their management, and almost all organizations emphasized the importance of measuring employees' performance and boosting it. Also, many of these companies have realized that employees who participate in their activities actively contributed to supporting their managers 'decisions. Moreover, encouraging employees to shoulder more responsibilities enhances their productivity and contributes to raising morale and commitment, and empowerment contributes to promoting innovation, creativity, and motivation and instills common values and creates an environment for learning and achievement.

Emerson (2008), aimed to find out the reasons that make employees' empowerment an issue that is not merely an aphorism or a buzz word, but it is a process that achieves job satisfaction and enhances workers' performance and thus helps accomplish the company's goals. The study stressed that administrations should be keen to practice and

encourage the method of empowering employees while keeping contact with employees and considering their views. The researcher also called to evaluate the means of mutual communication with their sub-ordinates. Employees should also have the freedom to express their views on the issues that concern them, and this makes them feel proud of the organization's appreciation of their efforts, ideas, and suggestions. As indicated by Rhadi (2010) who proved the direct relationship between creativity and empowering employees. The study population was targeted by selecting a random sample in order to ensure that there is no bias, and for the results to be faithfully expressive of the reality of administrative empowerment at Al-Ahliyya Amman University.

We hypothesize to test the effects of level of administrative empowerment and explaining its impact on the competency of institutional performance AAU. We test the level of administrative empowerment and explaining its impact on the competency of institutional performance AAU. To test our hypothesis. The data was collected from the (200) members working at AAU.

Table 1. Demographic aspects

Gender	Male	Female			
	79.5	20.5			
Age	Below 30	31-39	40-45	46-50	More than 51
	23.0	21.5	31.5	18.5	5.5
Education	Bachelor	High Diploma	Master	PhD	
	50.5	23.0	19.5	7.0	
Experience	0-5	6-10	11-15	More than 16	
	15.0	13.0	30.0	42.0	
Career Level	Senior management	Middle management	Executive management		
	20.5	53.5	26.0		
Job	Director	Deputy Director	Head of the Department	Employee	
	18.0	23.0	33.0	26.0	

Table 1 shows the demographic aspect of surveyed members of the AAU. Table 1 shows that most of management 79.5% were male and most of them 31.5% were from an age group of 40-45 years. Education profile shows that most of the respondents 50.5% are carrying the bachelor's degree and 19.5% and 7% are also carrying the highest degree Master and PhD respectively. To test the level of administrative empowerment and explaining its impact on the competency of institutional performance, data was collected from 20.5% Senior management and 53.5 Middle management and 26% Executive management. Lastly, the experience distribution shows that 42% have more than 16 years' experience and 30% for the experience of 11-15 years.

Table 2. Strength of relationship among the items in each construct

Measurement items		Mean	S.D.
Delegation Authority (DA) My direct manager in the AAU provides me with the necessary information and knowledge related to my job tasks. *(DA1)* The senior management of the AAU delegates some powers to the directors of the departments therein. *(DA2)* My direct manager in the AAU delegates the necessary powers to perform the duties required of me. *(DA3)* I am involved in decisions related to my work. *(DA4)* My line manager provides adequate support and advice on my delegated tasks. *(DA5)*	α: 85.8 *t*-Value: -1.001	4.3145	0.6894

AAU senior management works to give workers responsibility and decision-making. *(DA6)*

The AAU aims to involve all its employees for the success of the work. *(DA7)*

The senior management of the AAU focuses on the procedure whereby its employees are given the authority and authority to solve daily problems that arise during work. *(DA8)*

I have powers to correct deviations when they happen without referring to the immediate boss. *(DA9)*

The higher management of the AAU aims to give individuals greater authority in exercising oversight to increase their capabilities in the decision-making process. *(DA10)*

I have the freedom to perform the tasks entrusted to me and to discuss my ideas with the senior management of the AAU. *(DA11)*

Independence (IN)

α: 83.52   *t*-Value: 0.095

I have the opportunity to be proactive and independent in performing the required tasks. *(IN1)*

My line manager at the AAU trusts in my practical abilities to take on the responsibilities of my job. *(IN2)*

My position in the AAU provides opportunities to make independent decisions. *(IN3)*

The director of the department delegates sufficient powers to his assistants to accomplish their job duties. *(IN4)*

The line manager specifies the appropriate flexibility for subordinates to act in the performance of their job duties. *(IN5)*

4.1383   0.7169

The AAU is working to provide an appropriate degree of discretion to employees. *(IN6)*

The senior management of the AAU entrusts its employees with a degree of independence while holding them accountable for the results. *(IN7)*

The AAU is transferring enough powers to workers so that they can perform the tasks assigned to them freely. *(IN8)*

AAU's senior management encourages working individuals to take personal responsibility for developing the way they do their work. *(IN9)*

My line manager encourages me to take responsibility by delegating authority to make decisions at the lowest level. *(IN10)*

Learning and Training (LT)

α: 86.76   *t*-Value: 8.971

Staff is trained to cope with developments in the AAU. *(LT1)*

The AAU is working hard to find new ways to train and develop business methods. *(LT2)*

The AAU continuously conducts training courses for its employees. *(LT3)*

Training courses focus on improving the skills and capabilities of workers in the AAU. *(LT4)*

The results of the training courses are evaluated at the end of each training program. *(LT5)*

4.12961   0.6883

The period specified for the plans corresponds to the topics raised in the training program. *(LT6)*

The training material is prepared in light of the needs of the trainees. *(LT7)*

The AAU uses modern training methods to implement training programs. *(LT8)*

The AAU senior management adopts a clear training plan. *(LT9)*

The AAU provides various training courses to develop the skills of its employees. *(LT10)*

AAU employees have opportunities to learn and acquire new tasks in their field of work. *(LT11)*
Training helps to provide employee self-motivation to increase efficiency and improve productivity. *(LT12)*
Training plans are designed to address business problems and avoid any future imbalances. *(LT13)*

Institutional Performance (IP) AAU employees perform the tasks assigned to them according to the required quality standards. *(IP1)* Workers complete job tasks on time. *(IP2)* The AAU is keen to provide specific performance indicators for workers. *(IP3)* AAU employees can initiate and innovate. *(IP4)* The relationship of employees with their superiors is characterized by friendliness and harmony. *(IP5)* Workers are keen to use the capabilities and resources available by the AAU efficiently and effectively. *(IP6)* The AAU seeks to fulfill its obligations to society through service excellence. *(IP7)* The AAU is keen to develop its financial services in line with its social responsibilities. *(IP8)* The AAU seeks to simplify the work procedures. *(IP9)* The AAU is investing a lot of money in the rehabilitation and development of its human resources. *(IP10)* The AAU routinely develops its administrative procedures and technical practice. *(IP11)* The AAU possesses distinguished administrative competencies in the field of its main services. *(IP12)* The AAU carries out an assessment of the needs of the beneficiaries of its services provided periodically. *(IP13)* The AAU provides its services in response to the needs of the public. *(IP14)*	α: 77.82 *t*-Value: 1.066	
	4.1730	**0.70626**

Cronbach Alpha test is applied to test the strength of the relationship among the items in each construct. We find that all dependent and independent variables have Cronbach Alpha at least more than 0.80 except the Institutional Performance (IP) which has Cronbach Alpha 0.77.82. Moreover, our objective is to test the level of administrative empowerment and explaining its impact on the competency of institutional performance AAU. Cronbach Alpha value shows an excellent strength of the relationship. Overall, all the constructs are shown the validity to proceed for further analyses (Table 2).

Table 3. Regression dependent variable is the effectiveness of administrative decisions

Variable	Coeff	SE	t	P
Delegation Authority	-8.84E-02	0.088	-1.001	0.005
Independence	9.954E-03	0.104	0.095	0.001
Learning and training	1.014	0.113	8.971	0.000
Institutional Performance	0.324	0.304	1.066	0.000
The goodness of Fit (F-value)	70.049			0.000
R2	0.517			

The regression's result shows (Table 3) that the effects of **(DA)**, **(IN)**, and **(LT)** on the **(IP)** of the AAU are found positive and significant. So, the AAU efforts for **(DA)**, **(IN)**, and **(LT)** are found very helpful in improving the **(IP)** of the AAU. In comparison, the **(DA)** has the greatest effect on the **(IP)** of the AAU. It means that the AAU inputs in the **(DA)** are important for the **(IP)**. However, the magnitude of the effect of the **(IN) and (LT)**, is also found nearby to the magnitude of the **(DA)**. It means that **(IN) and (LT)**, of the AAU, also does matter equally in the impact of the level of administrative empowerment involving achieving the higher **(IP)**.

Conclusions & Recommendations

1. Focus on training workers at AAU to practice job empowerment, through implementing action plans for development purposes, develop annual plans for training, use effective methods such as lectures, and encourage workers to participate in training programs.
2. Adopt a strategy that realizes the application of modern management concepts in the AAU such as job empowerment, total quality management, and teamwork.
3. Grant rewards for the AAU for the working teams and involve workers in specialized programs on job empowerment.
4. Delegate authorities to employees at the AAU in a balanced manner that is relevant to their responsibilities.
5. Allow workers to participate in the process of decision-making and decision-taking at the AAU.
6. Develop the administrative skills of workers in AAU through raising their knowledge and awareness of modern management concepts.
7. Develop work procedures at the AAU to meet the requirements of job empowerment.
8. Assign a box to receive complaints and proposals from workers at the AAU to express their views and suggestions about the degree of the AAU senior management implementation of administrative empowerment, to what extent it delegates authorities to employees and enables them to behave independently.

Limitations and Future Recommendations

The conclusions derived from the findings of this study need to consider the following limitations:
1) This study was focused on four dimensions of administrative empowerment (delegating powers/devolution of authorities, independence, learning, and training) and did not include other factors that can influence institutional performance, such as knowledge sharing, team empowerment, and power distance.
2) the study questionnaire was distributed randomly to 200 respondents in general, it would give better results if we increase the number of respondents and focus more on the targeted respondents whether they are undergraduate or employed at AAU.
3) it is important to figure out that, when answering the questionnaire, respondents revealed their subjective perceptions which may limit the objectivity of the survey results.
4) the study findings are related to the specific country "Jordan" in which the research was conducted, the results may have limited generalizability a broad, therefore, more studies need to be considered in other regions on different sectors.

IMPROVING THE SOCIO-ECONOMIC WELL-BEING OF THE POPULATION IN RURAL AREAS IN THE CONTEXT OF IMPROVING THE ECONOMIC SECURITY OF THE STATE

Oleg V. Zakharchenko

Department of Management and Marketing, Odessa State Academy of Civil Engineering and Architecture, 65029, 4 Didrikhson Str., Odesa, Ukraine

E-mail: o.zakharchenko5206@nuos.pro

Abstract. Issues of improving the well-being of the population do not always belong to the category of strategic. In this case, the main value is determined by individual indicators that reflect the development of individual territories or industries. The relevance of the paper is determined by the ability of calculating indicators that form an idea of how well developed the socio-economic program of the territory development. The novelty of the study is determined by the fact that has been developed a model that allows to accumulate a number of formal indicators and thus not only specify the level of development of a particular territory or region, but also indicate the level of participation of private business in the development of socio-economic well-being. The authors include in the model the structure of socio-economic indicators that have a personal basis and can be used to develop programs and systems for computer modelling of the socio-economic development of the territory. The authors show that socio-economic well-being subsequently determines the level of economic security of the population. The practical significance of the study is determined by the capabilities of forecasting and applying indirect models for determining the socio-economic well-being of the population in the conditions of crisis conditions of the economy. It is proposed to use a set of balanced indicators of socio-economic development with a predominance of mathematical modelling patterns based on a set of market data.

Keywords: strategy; model; development; population; well-being

1. Introduction

The financial and economic sphere and related processes accompany us at every step of our daily lives (Kline et al., 2007). That is why their study, and especially the study of nonlinear non-stationary processes, requires more and more attention from the scientific community every day (Bryden et al., 2011; Fedotov et al., 2018). In particular, the issues of modelling and forecasting processes that, in the conditions of crisis phenomena of the economy and various external or domestic factors of influence, acquire new features and becoming increasingly relevant (Saqalli et al., 2011; Yessilov, 2015; Salimyanova et al., 2019). To obtain valid mathematical and statistical models, as well as high-quality forecasts, it is necessary to critically analyse, improve and use existing methods, for example, methods based on moving average autoregression (MAA) models, methods of optimal estimation and filtering, the method of group accounting of arguments and many others (Newburn & Berck, 2006). However, in order to achieve a significant improvement of the model and obtain a better forecast, neural networks of various modifications, non-standard regression approaches to modelling can be applied (Rushton, 1992; Bliznets et al., 2018; Pyagay et al., 2014; Bashynska et al., 2019).

The problems of mathematical modelling are becoming increasingly relevant for the effective organisation of management of individual business entities and economic communities due to the fact that the quality of decisions made is largely determined by the quality of forecasting their consequences. Therefore, the decisions made today should be based on reliable estimates of the possible development of the studied phenomena and events in the future (Johnson et al., 2010; Ermilova, 2018; Bashynska et al., 2020).

Forecasting is a tool that represents an opportunity within which realistic objectives for planning a subject's development strategy can be set (Hatherley et al., 2013). During forecasting, mathematical methods are used, which are sometimes quite complex and non-trivial. Due to the widespread use of computers that are easy to understand and use, and most importantly, effective forecasting programs, it has become a fast and fairly effective analysis mechanism (Do & Park, 2018). That is why the search for new or a combination of existing methods allows to get a more accurate and valid model, which in turn provides the opportunity to make effective management decisions (Leinbach & Cromley, 1989).

Today, there are many systems of various nature: environmental, technical, economic and financial, which function and develop under the influence of random disturbances of a different nature. And this in turn leads to the emergence of non-stationary processes – the emergence of a trend and heteroscedasticity (Eid & Hegazy, 1983). Non-stationary, as a rule, are accompanied by non-linear (Moldodikova et al., 1989). This necessitates the development and use of atypical approaches to modeling and forecasting the analysed processes (Gorbenkova et al., 2018). Vivid and well-known examples of such models are socio-economic indicators characterising the economic situation in a country (Refsgaard & Johnson, 2010). They describe non-linear behavior (Masduqi et al., 2010). Here the signs of unsteadiness are (Gronau et al., 2017):

–   structure of macroeconomic processes, which is unstable in time;
–   uncertainty of the future and critical values of the parameters of control processes;
–   complex formalisation of process dynamics.

Provided that not all the features will be taken into account, insufficient statistical sampling is possible when it is either impossible to conduct a correct analysis, assessment and valid forecasting of the dynamics of macroeconomic processes by classical methods, or the result will be of very poor quality (Rafindadi & Kondo, 2018; Kerimov et al., 2018a; Kerimov et al., 2018b).

2. Materials and Methods

The adequacy criteria of the model make it possible to separately assess the significance of the coefficients of the mathematical model in a statistical sense, to determine the integral error of the model relative to the initial time series, to establish the correlation between the values of the model error (they should not be correlated), and also to determine the degree of adequacy of the model to the physical process as a whole (Križanović et al., 2016). Consider the following statistical parameters: t – Student's statistic. The significance of each regression coefficient in a statistical sense is determined using t-test, which, as a rule, is calculated by all statistical software packages according to the formula:

$$t_a = \frac{\hat{a} - a_0}{SE_a} \tag{1}$$

where $\hat{a}$ – coefficient estimate obtained using the packet; a_o – null hypothesis regarding the value of this coefficient (usually $a_o=0$); SE_a – standard error of the estimate of the coefficient calculated in the packet.

Obviously, the lower the standard error, the better the estimate of the model coefficient (Müller & Munroe, 2005). To determine the significance of the coefficient, it is necessary to know the sample length N, the number of estimated parameters p and set the significance level α (usually set $\alpha=1\%$, $\alpha=5\%$, $\alpha=10\%$). A significance level of 5% means that when assessing the regression, we assume that erroneous decisions about the significance of the estimates are possible in 5% of cases. These parameters allow to select significances from the tables t_{crit}. When $t_{crit} < t_a < t_{crit}$ then the null hypothesis about the insignificance of the coefficient is accepted; otherwise, it is rejected and the coefficient is considered significant. Because the significance of statistics t_a inversely proportional to standard error SE_a, then the greater the significance t_a, the higher the value of a particular coefficient.

Determine coefficient R^2. The degree of informativeness of the time series often use its variance. Coefficient R^2 – this ratio of the variance of a part of the time series of the main variable is described by the resulting equation to the sample variance of this variable. It is calculated by the formula:

$$R^2 = \frac{var(\hat{y})}{var(y)} \tag{2}$$

For a valid model, the coefficient of determination should tend to unity, that is: $R^2 \rightarrow 1$. The sum of the squared errors of the model $\sum e^2(k)$, that is:

$$SSE = \sum_{k=1}^{N}[\hat{y}(k) - y(k)]^2 \tag{3}$$

Where N – sample length, measurement (4):

$$\hat{y}(k) = \hat{a}_0 + \hat{a}_1\hat{y}(k-1) + \hat{a}_2\hat{y}(k-2) + \hat{b}_1x(k) + b_2z(k); y(k) \tag{4}$$

Obviously, from the possible candidates it is necessary to choose the model for which $\sum e^2(k)$ takes the minimum value. Akaike Information Criterion (AIC). This criterion takes into account the sum of the squared errors, the number of measurements N and the number of estimated parameters p:

$$AIC = Nln\left[\sum_{k=1}^{N} - e^2(k)\right] + 2p \tag{5}$$

Obviously, for a better model, the criterion has lesser value, since it depends on the sum of the squared errors (SSE). However, in addition to SSE, this criterion takes into account the sample length and the number of estimated parameters, which makes it more informative. Durbin-Watson statistic. Durbin-Watson statistic are calculated using the formula:

$$DW = 2 - 2\rho \tag{6}$$

where ρ – correlation coefficient between random variable values $\varepsilon(k) \approx e(k)$, that is:

$$\rho = cov[e(k)] = E[e(k)e(k-1)] \tag{7}$$

This parameter allows to determine the correlation degree of model errors. In the complete absence of correlation between the errors $DW = 2$, this is the most acceptable value of this parameter. Fisher statistics F, which determines the validity degree of the model as a whole. For a valid model, the condition: $F > F_{crit}$, where F_{crit} determined by the table similar to t-statistics. Thus, a more valid model corresponds to a larger F value. The Tail coefficient is a very important indicator of model accuracy and compatibility:

$$U = \frac{\sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}}{\sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i)^2} + \sqrt{\frac{1}{N}\sum_{i=1}^{N}(\hat{y}_i)^2}} \tag{8}$$

When building, its value is between 0 and 1. If $U = 1$, the model cannot be used for forecasting. Predicted, based on the obtained model, real series are not correlated. Otherwise, if $U = 0$, the predicted series coincide with the real series and the model is most preferable.

3. Results and Discussion

This coefficient can be broken down into the sum of the ratio U^M, the ratio of variations U^S, and the covariance ratio U^C:

$$U^M = \frac{(y_i - \hat{y}_i)^2}{\frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2} \tag{9}$$

U^M is used to check for systematic deviations for average real and predicted series. Or, in other words, the model constantly overestimates the forecast. The lower the value U^M the better. If $U^M=0$, then in the predicted values there is no bias and the model is qualitative. U^S – the ratio of variations and is defined as:

$$U^M = \frac{\left(\sigma_{actual} - \sigma_{fitted}\right)^2}{\frac{1}{N}\sum_{i=1}^{N}\left(y_i - \hat{y}_i\right)^2} \tag{10}$$

The ratio of variations is used to verify that the model has enough dynamic properties to absorb variations of real series. For example, a model can provide systematically smaller oscillations than oscillations of real series. Similarly, U^M, lower values of U^S are an indicator of less variations. U^C – the ratio of covariances and is defined as:

$$U^C = \frac{2(1-\rho)\left(\sigma_{actual} - \sigma_{fitted}\right)^2}{\frac{1}{N}\sum_{i=1}^{N}\left(y_i - \hat{y}_i\right)^2} \tag{11}$$

Covariance ratio U^C measures how correlated the predicted and real series are. Equivalence of U^C to zero indicates that the predicted and real series are perfectly correlated. It should be noted that:

$$U^C + U^C + U^C = 1 \tag{12}$$

To evaluate the model, it is necessary to determine how well the model reproduces real time series. It is always recommended to make a repeated (retrospective) forecast after modelling. The formal criteria for evaluating the forecast are: formal statistics; turning points (inflection points); sensitivity to changes in the source data; sensitivity to changes in coefficients. Root mean square error (RMSE):

$$RMSE = \sqrt{\frac{1}{S}\sum_{i=1}^{S}\left(y(k+s) - \hat{y}(k+s,k)\right)^2} \tag{13}$$

Average forecast error (AFE):

$$AFE = \frac{1}{S}\sum_{i=1}^{S} y(k+s) - \hat{y}(k+s,k) \tag{14}$$

Average error in percent (PAE):

$$PAE = \frac{1}{S}\sum_{i=1}^{S}\frac{y(k+s) - \hat{y}(k+s,k)}{y(k+s)} \times 100\% \tag{15}$$

Absolute average error in percent (AAE):

$$AAE = \frac{1}{S}\sum_{i=1}^{S}\frac{|y(k+s) - \hat{y}(k+s,k)|}{|y(k+s)|} \times 100\% \tag{16}$$

Maximum absolute error (MAE):

$$MAE = max\{|y(k+1) - \hat{y}(k+1,k)|, \ldots, |y(k+s) - \hat{y}(k+s,k)|\} \qquad (17)$$

Minimum absolute error (MIAE):

$$MIAE = min\{|y(k+1) - \hat{y}(k+1,k)|, \ldots, |y(k+s) - \hat{y}(k+s,k)|\} \qquad (18)$$

Estimating models by inflection points is an important indicator, as some models may have greater accuracy, but there may be cases where they may not work well in predicting changes in trends or cycles. Other models may be less accurate, but may exhibit a higher dynamic character. We can talk about a compromise between accuracy and dynamic properties. Unfortunately, there is no formula test for these properties. However, a visual check of the predicted and real series quickly determines if the model includes inflection points. Another important test of the quality of the model is the analysis of sensitivity to the initial (starting) data. If the model gives results that are generally roughly independent of the initial data, then this model is considered to be of high quality.

To create an adaptive forecasting system, it is necessary to choose a process, analyse its current state, existing models and approaches to its forecasting. An analysis of specialised literature can greatly help in finding an existing model to describe the behaviour of a selected process. For example, we can find mathematical models in the form of systems of equations, laws of distribution of input and output quantities (statistical models), or logical models in the form of sets of rules that characterise the interaction of inputs and outputs. Recently, probabilistic methods and models of various structures, as well as models in the form of fuzzy logic rules, have become more and more widespread and popular. To implement the further stages of creating predictive and control systems, a choice is made of the type and structure of the model (Kuznetsov et al., 2018; Lapidus et al., 2018a; Lapidus et al., 2018b).

For example, consider a model that is created on the basis of theoretical concepts and patterns regarding a specific process. It may require only clarification of its parameters, which can be obtained using statistical data. And in another case, a model that is completely based on statistical studies may require significantly larger amounts of information and time to build it. It is also necessary to inspect other specialised literature, but we need to know the features of the selected methods and the boundaries of their application. The software product obtained this way is the simplest in terms of architecture. That is why the use of this software product will be appropriate, convenient and profitable in organisations that do not have in-depth knowledge of computer programming. The architecture of the simulated software product has the following levels (Fig. 1).
Fig. 1. Architecture levels of the simulated software product

Consider each of these levels: data is loaded at the first level; at the second level, it is possible to visually evaluate data, conduct statistical, correlation analysis, analysis for non-linearity and non-stationarity; at the third level, models are built; at the fourth level, forecasting is based on the created model. It is also possible to depict a functional diagram that expresses the content of the simulated software product (Fig. 2).

To analyse and build models and forecasts, four time series were chosen: USD/CHF (208 values), CPI (60 values), LTV (107 values) and RST (100 values). USD/CHF (US Dollar/Swiss Franc) is a currency pair consisting of the US dollar and Swiss franc. On traders' slang, this pair is also known as Swiss. This pair is in fifth place among the most traded currencies on the market and is the world's reserve currency. USD/CHF is considered a safe haven for traders due to the economic stability and the neutral political nature of Switzerland. As data we take the minimum weekly prices of the USD/CHF currency pair (208 values) from 2016 (Fig. 3).
Fig. 2. Functional diagram of a simulated software product
Fig. 3. USD/CHF series

Statistical characteristics of the USD CHF series: average 1.2107; dispersion 0.0005; asymmetry coefficient 0.2803; excess 2.4929; Jacques-Berah 4.9518. CPI – Consumer Price Index (CPI) characterises the changes over time of the general price level for goods and services that the population buys for non-productive consumption. It is an indicator of changes in the cost of a fixed set of consumer goods and services in the current period to its value in the base period.

CPI (Fig. 4) is the most important indicator that characterises inflationary processes in the country's economy and is used to solve many issues of state policy, analyse and forecast price processes in the economy, review the size of cash incomes and minimum social guarantees of the population, resolve legal disputes, recount indicators system of national accounts at constant prices.
Fig. 4. CPI series (consumer price index)

Statistical characteristics of the CPI series: average 100.35; dispersion 1.5534; asymmetry coefficient 0.2599; excess 3.4014; Jacques-Berah 1.0785. Gross revenue is the amount of money a company receives as a result of doing business, and expenses are not taken into account. For example, a retailer receives revenue from the sale of goods, but the gross revenue does not include the cost of acquiring goods from suppliers, labor costs for employees, overhead associated with running a business, and the lost revenue from returning goods or theft. Gross revenue refers only to the amount of income received only from the sale of goods or services, or from other sources of income, such as royalties and investments, excluding related costs. It should be noted that gross revenue is not the main indicator for many companies, although in some situations it is of great importance (Fig. 5).

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810
Fig. 5. GR series (Gross Revenue) Apple Inc, 2004-2019

Since this indicator does not reflect the costs associated with doing business, it does not always reflect how efficiently the company operates. In professional language, gross revenue is sometimes called the "Top Line", since this indicator is usually placed at the top of various financial statements. At the same time, expense items associated with the conduct of activities are placed below this indicator (Fig. 6). Statistical characteristics of Gross Revenue: average 14380.36; dispersion 527119888.4945; asymmetry coefficient 0.7334; excess 2.7167; Jacques-Berah 10.0439. RST – net profit.
Fig. 6. RST series (average per employee, 2000-2020)

521

Statistical characteristics of the RST series: average 0.2634; dispersion 23.69521; asymmetry coefficient 0.5483; excess 4.3794; Jacques-Berah 12.9377. First, consider the possibility of describing the selected processes using the autoregressive model. Autoregressive models are the simplest in their structure, but quite often they have a high degree of validity to the process under study, acceptable for further use. We build an autoregressive model for the USD/CHF series: autoregression of the 14-th order:

$$y(k) = 0,0133 + 0,9655^*y(k-1) + 0,0099^*y(k-2) +$$
$$+0,0319^*y(k-3) - 0,1146^*y(k-4) + 0,0521^*y(k-5) +$$
$$+0,1001^*y(k-6) - 0,0682^*y(k-7) - 0,0918^*y(k-8) +$$
$$+0,0995^*y(k-9) + 0,1130^*y(k-10) - 0,1521^*y(k-11) +$$
$$+0,0017^*y(k-12) + 0,0472^*y(k-13) - 0,0057^*y(k-14) \tag{19}$$

Therefore, statistical characteristics of the model: $R^2 = 0,9516; \sum e^2 = 0,00459; DW = 1,9692$. The determination coefficient takes on values (0.9516), the sum of the squared errors is very small (0.00459), and the Durbin-Watson statistic (1.9692) is approaching the best value. The quality characteristics (for the training sample) for the forecast of the selected series RMSE = 0.003473; PAE = 4.2%. (Fig. 7):
Fig. 7. Forecast for USD/CHF

That is, the root means square error (RMSE) and the average error in percent (PAE) indicate the general suitability of the forecasting model. Next, we will build another model for the USD/CHF series: 5-th order autoregression:

$$y(k) = 0,0140 + 0,9637 * y(k-1) - 0,0114 * y(k-2) + 0,0832 *$$
$$* y(k-3) - 0,1271 * y(k-4) + 0,0796 * y(k-5) \tag{20}$$

Therefore, statistical characteristics of the model: $R^2 = 0,9541; \sum e^2 = 0,00463; DW = 2,0024$. The coefficient of determination takes on values (0,9541), the sum of the squared errors is very small (0.00463), and the Durbin-Watson statistic (2.0024) is approaching the best value. The quality characteristics (for the selected row RMSE=0,003778; PAE=4,524% (Fig. 8).

Fig. 8. Forecast for USD/CHF

That is, the root means square error (RMSE) and the average error in percent (PAE) indicate the general suitability of the model for forecasting. Here is a general table of model quality estimates and forecast for a series of USD/CHF (Table. 1).

Table 1. Results of modelling and forecasting for a series of USD/CHF according to various quality criteria

Statistical series	Model type	Model validity			Forecast characteristic	
		R^2	$\sum e^2$	DW	RMSE	PAE %
USD/CHF	AR(14)	0.9516	0.00459	1.9692	0.003473	4.2
	AR(5)	0.9541	0.00463	2.0024	0.00378	4.524

As can be seen from the table, the AR showed the best in terms of forecast quality and model quality (14). We will build an autoregressive model for the CPI series: 15-th order autoregression:

$$y(k) = 43,266 + 0,6589^*y(k-1) - 0,4392^*y(k-2) + 0,4476^*y(k-3) -$$
$$-0,1289^*y(k-4) - 0,0756^*y(k-5) + 0,0068^*y(k-6) - 0,0273^*y(k-7) -$$
$$-0,0604^*y(k-8) - 0,0178^*y(k-9) + 0,1186^*y(k-10) - 0,0039^*y(k-11) +$$
$$+0,5238^*y(k-12) - 0,3695^*y(k-13) + 0,1725^*y(k-14) -$$
$$-0,2428^*y(k-15) \tag{21}$$

Therefore, statistical characteristics of the model: $R^2 = 0,544; \sum e^2 = 0,696; DW = 2,035$. The determination coefficient takes on values (0.544), the sum of the squared errors is very small (0.696), and the

Durbin-Watson statistic (2.035) is approaching the best value. The quality characteristics (for the training selection) for the forecast of the selected series RMSE = 1,0504; PAE = 3.28% (Fig. 9).
Fig. 9. Forecast for CPI

That is, the root means square error (RMSE), the average error in percent (PAE) indicates the general suitability of the model for forecasting. Next, it is necessary to build another autoregressive model for the CPI series: autoregression of 3-rd order with a moving average value of 5:

$$y(k) = 27{,}1206 + 1{,}1446^*y(k-1) - 0{,}7030^*y(k-2) + 0{,}2875^*y(k-3) -$$
$$-0{,}4281^*v(k-1) + 0{,}0572^*v(k-2) + 0{,}2875^*v(k-3) - 0{,}156^*v(k-4) -$$
$$-0{,}3263^*v(k-5) \tag{22}$$

Therefore, statistical characteristics of the model: $R^2 = 0{,}9496; \sum e^2 = 1{,}038; DW = 2{,}7359.$ The

determination coefficient takes on values (0.9496) better than the previous one, the sum of the squared errors (1.038) shows a certain deterioration according to preliminary results, and the Durbin-Watson statistic (2.7359) showed poor results and a significant deterioration with previous models. The quality characteristics (for the training selection) for the forecast of the selected series RMSE = 0.909; PAE = 2.81% (Fig. 10).

Fig. 10. Forecast for CPI

The root means square error (RMSE), the average error in percent (PAE) decreased compared to the previous result. Here is a general table of model quality estimates and forecast for a CPI series (Table. 2):

Table 2. Results of modelling and forecasting of the consumer price index by various quality criteria

Statistical series	Model type	Model validity			Forecast characteristic	
		R^2	$\sum e^2$	DW	RMSE	PAE%
CPI	AR(14)	0.544	0.696	2.035	1.0504	3.28
	MAA(3.5)	0.9496	1.038	2.7359	0.909	2.81

The constructed MAA model (3.5) had good results, but the Durbin-Watson statistic was 2.7359, which is a big deviation, but the forecast is of high-quality. We will build an autoregressive model for the RST series: 14-th order autoregression:

$$y(k) = 0,0974 + 1,1098y(k-1) + 0,1776^*y(k-2) +$$
$$+0,0297^*y(k-3) - 0,0054^*y(k-4) + 0,1289^*y(k-5) +$$
$$+0,0809^*y(k-6) - 0,0747^*y(k-7) - 0,1301^*y(k-8) +$$
$$+0,3111y(k-9) + 0,0717y(k-10) - 0,0392^*y(k-11) +$$
$$+0,1999^*y(k-12) + 0,3538^*y(k-13) - 0,367^*y(k-14) \tag{23}$$

Therefore, statistical characteristics of the model: $R^2 = 0,91; \sum e^2 = 1,567; DW = 1,946.$ The determination

coefficient takes on values (0.91), the sum of the squared errors (1.567), and the Durbin-Watson statistic (1.946). The quality characteristics (for the training selection) for the forecast of the selected series RMSE=2.22; PAE=3.84% (Fig. 11):
Fig. 11. Forecast for RST

Next, we will build another autoregressive model for the RST series: autoregression of the 5-th order:

$$y(k) = 0{,}0504 + 1{,}0972 * y(k-1) - 0{,}1664 * y(k-2) + 0{,}0086 *$$
$$* y(k-3) - 0{,}0031 * y(k-4) + 0{,}118 * y(k-5) \qquad (24)$$

Therefore, statistical characteristics of the model: $R^2 = 0{,}881; \sum e^2 = 1{,}7161; DW = 2{,}0003.$ The coefficient of determination takes on the value (0.881), a certain deterioration with the previous results, the sum of the squared errors takes on the value (1.7161), and the Durbin-Watson statistic (2,0003). The quality characteristics (for the training selection) for the forecast of the selected series RMSE=3.084; PAE=5.7% (Fig. 12):
Fig. 12. Forecast for RST

Next, build another autoregressive model for the RST series: autoregression of the 14-th order with a moving order average of 6:

$$y(k) = -,1694 + 0,7666^*y(k-1) - 0,2212^*y(k-2) + 0,0918^*y(k-3) +$$
$$0,6318^*y(k-4) - 0,0669^*y(k-5) - 0,0281^*y(k-6) - 0,3432^*y(k-7) -$$
$$-0,0723^*y(k-8) + 0,1748^*y(k-9) - 0,0125^*y(k-10) + 0,1072^*y(k-11) -$$
$$-0,0728^*y(k-12) + 0,2445^*y(k-13) - 0,447^*y(k-14) + 0,3569^*v(k-1) +$$
$$+0,3941^*v(k-2) + 0,3301^*v(k-3) - 0,4632^*v(k-4) - 0,3127^*v(k-5) -$$
$$-0,3943^*v(k-6) \tag{25}$$

Therefore, statistical characteristics of the model: $R^2 = 0,9357; \sum e^2 = 2,0124; DW = 1,144.$ The determination coefficient takes on values (0.9357), the sum of squared errors (2.0124), and Durbin-Watson statistic (1.144) showed a significant deterioration in the results. The quality characteristics (for the training selection) for the forecast of the selected series: RMSE=4.306; PAE=6.18%. The root means square error (RMSE), the average error in percent (PAE) decreased compared to the previous result. Since the series is heteroscedastic, we construct a 5th-order autoregressive model with a quadratic trend (Table 3).

Table 3. Evaluation results of the AR (5) model with a quadratic trend for the RST series

	Coefficient	Std. Error	t-Statistic	Prob.
C(1)	0.540648	0.742731	0.727919	0.4686
C(2)	1.060074	0.107005	9.906769	0.0000
C(3)	-0.168990	0.156169	-1.082099	0.2822
C(4)	0.009839	0.158695	0.061999	0.9507
C(5)	0.005448	0.157561	0.034579	0.9725
0(6)	-0.025252	0.107743	-0.234377	0.8152
C(7)	-0.040421	0.034520	-1.170945	0.2448
0(8)	0.000466	0.000329	1.415894	0.1604
R-squared	0.886090	Mean dependent var		0.236716
Adjusted R-squared	0.876925	S.D. dependent var		5.019531
S.E. of regression	1.760954	Akaike info criterion		4.050040
Sum squared resid	29.78344	Schwarz criterion		4.265104
Log likelihood	-184.3769	Hannan-Quinn criterion		4.136942
F-statistic	96.68033	Durbin-Watson statistic		2.001821
Prob(F-statistic)	0.000000			

As a result, the following model was obtained:

$$y(k) = 0,541 + 1,06^*y(k-1) - 0,169^*y(k-2) + 0,0098^*y(k-3) +$$
$$+0,0054^*y(k-4) - 0,02525^*y(k-5) - 0,040^*k + 0,00046^*k^2 \tag{26}$$

The validity of the model is estimated by the following parameters: $R^2 = 0,886; \sum e^2 = 29,7834; DW = 2,001.$ The determination coefficient takes on values (0.886), the sum of the squared errors (29.7834) showed a big value, and the Durbin-Watson statistic (2.001) are almost ideal. The

quality characteristics (for the training selection) for the forecast of the selected series RMSE=3.948; PAE=5.9%. Here is a general table of model quality estimates and forecast for a number of RST (Table 4).

Table 4. Results of modelling and forecasting of RST series

Statistical series	Model type	Model validity			Forecast characteristic	
		R^2	$\sum e^2$	DW	RMSE	PAE%
RST	AR(14)	0.91	1.567	1.946	2.22	3.84
	AR(5)	0.881	1.7161	2.0003	3.084	5.7
	MAA(14.6)	0.9357	2.0124	1.144	4.306	6.18
	AR(5)+k2	0.886	29.7834	2.001	3.948	5.9

The best results in forecasting, i.e., with the slightest errors, were shown by the AR (14) model. We build an autoregressive model for the GR series: autoregression of the 13-th order:

$$y(k) = -23{,}2267 + 0{,}8006^*y(k-1) - 0{,}0204^*y(k-2) + 0{,}1980^*y(k-3) - \\ -0{,}0778^*y(k-4) - 0{,}1195^*y(k-5) - 0{,}0915^*y(k-6) + 0{,}049^*y(k-7) + \\ +0{,}1996^*y(k-8) - 0{,}019^*y(k-9) + 0{,}0661^*y(k-10) - 0{,}0583^*y(k-11) + \\ +0{,}6971^*y(k-12) - 0{,}5836^*y(k-13)$$

(27)

Therefore, statistical characteristics of the model: $R^2 = 0{,}97; \sum e^2 = 1180{,}84; DW = 2{,}09.$ The coefficient of determination takes the value (0.97), the sum of the squared errors (1180.84), and the Durbin-Watson statistic (2.09). The quality characteristics (for the training selection) for forecasting the selected series RMSE=1760.38; PAE=1.88%. Next, we build a different autoregressive model for the GR series: autoregression of the 9-th order:

$$y(k) = -58{,}2995 + 0{,}6005^*y(k-1) + 0{,}1344^*y(k-2) + 0{,}2679^*y(k-3) + \\ +0{,}0205^*y(k-4) - 0{,}2479^*y(k-5) - 0{,}3625^*y(k-6) + 0{,}1359^*y(k-7) + \\ +0{,}3401^*y(k-8) - 0{,}1689^*y(k-9)$$

(28)

Therefore, statistical characteristics of the model: $R^2 = 0{,}954; \sum e^2 = 1515{,}07; DW = 2{,}0013.$ The determination coefficient takes the value (0.954), a certain deterioration with previous results, the sum of the squared errors takes the value (1515.07), and the Durbin-Watson statistic (2.0013). The quality characteristics (for the training selection) for the forecast of the selected series RMSE=2947.597; PAE=3.152%. Next, we build another autoregressive model for the GR series: autoregression of the 13-th order with an average order value of 2:

$$y(k) = 101{,}5948 + 1{,}1018^*y(k-1) + 0{,}0192^*y(k-2) + 0{,}0438^*y(k-3) - \\ -0{,}1646^*y(k-4) - 0{,}1465^*y(k-5) - 0{,}0244^*y(k-6) + 0{,}1603^*y(k-7) + \\ +0{,}2244^*y(k-8) - 0{,}1407^*y(k-9) - 0{,}0131^*y(k-10) - 0{,}0728^*y(k-11) + \\ +0{,}7389^*y(k-12) - 0{,}7314^*y(k-12) - 0{,}3671^*v(k-1) - 0{,}3632^*v(k-2)$$

(29)

Therefore, statistical characteristics of the model: $R^2 = 0{,}987; \sum e^2 = 1296{,}48; DW = 2{,}393.$ The determination coefficient takes on values (0.987), the sum of squared errors (1296.48), and Durbin-Watson statistic showed a significant improvement in the results. The quality characteristics for the forecast of the selected series RMSE=3315.991; PAE=8.4%. The root means square error (RMSE), the average error in percent (PAE) remained with a positive result. Here is a general table of model quality assessments for forecasting for GR series (Table 5),

Table 5. Results of modelling and forecasting of GR series

Statistical series	Model type	Model validity			Forecast characteristic	
		R^2	$\sum e^2$	DW	RMSE	PAE%
GR	AR(13)	0.97	1180.84	2.09	1760.38	1.88
	AR(9)	0.954	1515.07	2.0013	2947.59	3.152
	MAA(13.2)	0.987	1296.48	2.393	3315.99	8.4

The best results in the forecasting, that is, the AR (13) model with small errors. Based on the results of previous studies, we build models of selected processes using the commercial product GMDH Shell, which uses the group argument method to build models. We analyse and predict the range of USD_CHF. Obtained model:

$$Y1[t] = -0.44331 + time^*(-0.000169013) + "x1[t-12], cubert"^* 1.56472 \qquad (30)$$

The coefficient of determination takes on the value of 0.628. The forecast characteristic of this series assumes the following values RMSE=0.498; PAE=1.278%. We analyse and forecast the consumer price index. Obtained model:

$$Y1[t] = 316.384 + "x1[t-5], cubert"^*(-37.8545) + "x1[t-3], cubert"^*(-8.68243) \qquad (31)$$

The coefficient of determination takes on the value of 0.45712. The forecast characteristic of this series assumes the following values RMSE=0.7747; PAE=0.61524%. As we can see, the forecast indicators give a high average absolute error in percent (PAE) which amounted to only 0.615%. It can be concluded that the model is suitable for use. Here is a model that is built for the RST series:

$$Y1[t] = 0.998017 + "x1[t-1], cubert"^*3.22661 + "x1[t-3], cubert"^*1.09025 +$$
$$+"x1[t-8], cubert"^*(-1.20318) + "x1[t-11], cubert"^*(-0.428972) + "x1[t-12],$$
$$cubert"^*0.412343 + "x1[t-4], cubert"^*0.506062 \qquad (32)$$

The determination coefficient of this model is 0.916219. The forecast characteristic of the RST series is as follows: RMSE=2.66394; PAE=5.27816%. Unfortunately, the forecast indicators are not sufficient, the PAE is 5.27816%. Consider the GR series:

$$Y1[t] = -4293.15 + "x1[t-1]^* + x1[x-12]^*3.99777e - 05 + x1[t-7]^{*"}x1[t-8],$$
$$cubert"^*0.0162273 + x1[t-3]^*x1[t-10]^*1.29137e - 05 +$$
$$x1[t-2]^{*"}x1[t-3], cubert"^*(-0.00356083) \qquad (33)$$

The determination coefficient of this model is 0.975549. The forecast characteristics of the GR series are as follows: RMSE=816.485; PAE=1.5856%. Here is a summary table for the estimates of the selected series (Table 6).

Table 6. Summary estimation table of selected series

Statistical series	Model type	Model validity			Forecast characteristic	
		R^2	$\sum e^2$	DW	RMSE	PAE%
USDCHF	AR(14)	0.9516	0.00459	1.9692	0.003473	4.2
	AR(5)	0.9541	0.00463	2.0024	0.00378	4.524
	GMDH	0.628			0.498	1.278
CPI	AR(15)	0.544	0.696	2.035	1.0504	3.28
	MAA(3.5)	0.9496	1.038	2.7359	0.909	2.81
	GMDH	0.45712			0.7747	0.61524
RST	AR(14)	0.91	1.567	1.946	2.22	3.84
	AR(5)	0.881	1.716	2.0003	3.084	5.7
	MAA(14.6)	0.9357	2.012	1.144	4.306	6018
	AR(5)+k2	0.886	29.783	2.001	3.948	5.9
	GMDH	0.91621			2.6639	5.2781

	AR(9)	0.954	1515.07	20013	2947.59	3.152
	MAA(13.2)	0.987	1296.48	2.393	3315.99	8.4
	GMDH	0.976			816.485	1.5856

Conclusions

In order to maximise the reliability and accuracy of the forecast values, modelling was carried out on the basis of several models, after which a corresponding comparative analysis was performed. Prediction of time series was carried out on the basis of autoregressive models, and autoregressive models with moving average, and the method of group accounting of arguments. As a result of modelling based on these methods, it can be concluded that there are no universal methods for constructing and predicting time series. Each row is unique in its own way, and each one requires its own balanced approach. It can also be concluded that during modelling it is impossible to rely only on one parameter of model validity, each of these parameters is important for the calculations and forecasting.

The quality of the constructed model largely depends on the correct application of methods for estimating model parameters. As in linear and non-linear processes, parameters can be estimated using the least squares method, the maximum likelihood method, the Monte Carlo method for Markov chains. Nonlinear methods require setting initial conditions and controlling the convergence of the estimation process. The Monte Carlo method for Markov chains is characterised by flexibility of application, but it may take a long time to implement.

Abstract. The European Union (EU) is implementing the concept of the circular economy (hereafter – CE) system, the main idea of which is to maintain the added value in products for as long as possible both to improve the quality of the environment and eliminate waste. These provisions presuppose the improvement of EU waste management systems and legal regulation. The European Commission proposed a legislative package for amending the main Directives related to waste management. The European Parliament and the Council adopted this document in 2018. The legislative package amends six Directives, which are the main components of the legal framework for waste management in the EU. These are systematic changes in EU waste law regulation and include: the modification of the waste management system; the alignment of definitions; and the formulation of new legal definitions (for example municipal waste, backfilling) or establishment of qualitative and quantitative indicators which cover the meaning of waste hierarchy. The aim of this article is to divulge the main legal changes, and to evaluate their content in the context of the concept of the CE.

1. Introduction

Over the last 5 years there has been an unprecedented speed of development in, on the one hand, such phenomena as Industry 4.0 and, on the other, the legal regulation of environmental protection. Today's economy, in the context of Industry 4.0, is based on digitization, technological development, big data, nanotechnology, and smart intelligence, and determines the development of industry activities whilst increasing consumption. The phenomena mentioned presuppose an increase in the use of natural resources and waste generation. The amount of waste generated and the disproportionate use of natural resources are factors that contribute to environmental degradation. The Treaty on the Functioning of the European Union (hereinafter – TFEU; Articles 11, 114, 191–193) divulges certain objects of environmental protection: the quality of the environment, human health, natural resources, and climate change. We can also include city and country planning, water resources, and land use as, according to L. Kramer, "environment is not limited to natural elements, but also covers man-made environment" (2012, pp. 9–11). Waste management, as a systematic phenomenon, impacts environmental and social problems in a comprehensive manner.

Firstly, waste management (as a system) is a source of air, land, and water pollution. As an example, waste disposal activities include: depositing into or onto land, taking up land space and impacting the quality of air and soil; releasing waste into seas/oceans, impacting water quality; incineration on land or at sea, or variant physical–chemical or biological treatments, which may result in the emission of air pollutants. This means that waste management significantly affects the environment, and has serious impacts on the degradation of the whole ecosystem (Eurostat, 2019; Tvaronavičienė, 2016).

Secondly, the management of waste is related to climate change. According to the European Environment Agency's statistical data, air pollution and climate change are intertwined. Several air pollutants are also climate forcers, which have potential impacts on climate change and global warming in the short term (Limba, Novikovas, Stankevičius, Andrulevičius, & Tvaronavičienė, 2020). For example, waste contributes a significant amount of CH_4 emissions (European Environmental Agency, 2018).

Thirdly, waste management affects the utilization of natural resources and ensures the recovery of resources. According to Eurostat (2019), waste potentially represents an enormous loss of resources in the form of both materials and energy. Recycled materials are "secondary raw materials", which are injected back into the economy as new raw materials. Waste management practices have a direct impact on the quantity and quality of these materials (European Commission, 2015a).

Fourthly, the waste management sector impacts on market costs and the economic system. Pollution (for example of the air) determines both market costs and non-market costs. Market costs include reduced labour productivity, additional health expenditure, and losses in both crop and forest yields. Non-market costs are those associated with increased mortality and morbidity (causing illness, for example, and resulting in pain and suffering), the degradation of air and water quality and consequently the health of ecosystems, as well as climate change (European Environmental Agency, 2018). On the other hand, resource efficiency improvements could represent an overall savings potential of €630 billion per year for European industry and material cost saving opportunities for EU industry, boosting EU GDP by up to 3.9% (European Commission, 2014).

Fifth, the waste management sector exists as a critical piece of infrastructure and forms part of the security phenomena. The waste management system interacts with economic, ecological, and national security issues (Novikovas & Stankevičius 2018).

The implementation of the circular economy model at the EU level started in 2014–2015, emphasizing ideas of environmental protection and sustainable development. The concept of sustainable development was first introduced in 1987 in the report by United Nations World Commission on Environment and Development (1987) called *Our Common Future* as a "development that meets the needs of the present without compromising the ability of future generations to meet their own needs". According this report, sustainable development contains two key concepts: the concept of *needs*, in particular the essential needs of the world's poor, to which overriding priority should be given; and the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs. Research papers divulge the concept of sustainability into the triple bottom line (3BL), which encompasses three pillars of sustainability: economic, social, and environmental (Elkington, 1997). Environmental responsibility in the form of environmentally friendly and more efficient processes enables potential differentiation for businesses. Product and process innovations allow for additional benefits, including cost savings. From this point of view, environmental responsibility should be seen as a competitive advantage and not only as an inconvenient cost (Moumen, El Idrissi, Tvaronavičienė, & Lahrach, 2019; Pechancová, Hrbáčková, Dvorský, Chromjaková, & Stojanovicet, 2019).

The main idea of the Circular Economy Action Plan, (European Commission, 2015a) is to boost and create new jobs, for growth and investment, and to develop a carbon-neutral, resource-efficient, and competitive economy. It provides for a new approach to municipal waste management, a transition from the linear model "take, produce, throw away", to the circular economy model "waste prevention, eco-design, re-use, recycling and creating a circle market cycle" (Limba et al., 2020). The environmental protection concept, according to the CE phenomena, includes conventional consumer habits which "can also hinder new products and services development". Such barriers tend to persist in a context where prices do not reflect the real costs of resource use to society, and where policy fails to provide strong and consistent signals for the transition to a CE (European Commission, 2014). According to research papers, CE is understood as a system where the value is created by minimizing waste and the use of energy and natural resources (Tura et al., 2019). This is achieved by utilizing models for slowing, closing and narrowing loops of material and energy flows regeneratively, and following the principles of reduce, reuse, and recycle (Geissdoerfer, Savaget, Bocken, & Hultinket, 2017; Langen & Sornn-Friese, 2019; Sauvé, Bernard, & Sloan, 2016).

2. Methodology

The aim of this article is to divulge the main legal changes in EU waste regulation and to evaluate the content of these changes in the context of the CE concept. The aim of the article will be realized through the following objectives:

- To reveal the theoretical framework of CE in the context of legal regulation;
- To assess systemic legal developments on the basis of the Proposal Package on waste management in the EU, according to the CE concept;
- To reveal basic legal categories of change on waste management
- To disclose the main characteristic of these legal changes.

The research is based on such methods as document analysis, statistical data analysis, historical, linguistic, logical, and systematic analysis. The data for this paper were gathered according to the key words (*circular economy*, *waste management*, *waste hierarchy*, *municipal waste*, and *waste*), using the methods of document analysis and statistical data. The authors relied on databases, such as those of Web of Science or Scopus, Eurostat, European Environmental Agency, the Court of Justice of the European Union (hereinafter – CJEU), and the Publications Office of the EU, which provide quality data and information for conducting research of this nature.

The selected data, such as scientific literature, legal acts, and case-studies, were processed using content analysis. Using this method, the authors revealed legal categories related to the object of the topic. The linguistic (Latin lingua-language) method was used to reveal the meanings of the definitions by analysing the texts of scientific literature, the caselaw of CJEU, and legal documents. Using the historical method, the authors discussed the meaning of concepts such as waste, circular economy, and waste hierarchy throughout historical developments. A logical–systematic and linguistic analysis of the provisions of the legal acts related to the object of study, assessing them in the context of all other provisions of the legal regulation relevant to the dispute and taking into account the objectives pursued by the legal regulation, allowed for the reasonable formulation of conclusions.

3. The analysis of the concept and package of documents of circular economy

As mentioned above, the EU established a political commitment which enabled the transition from a linear model to a circular economy plan, outlining a new approach to waste management. It should be noted that this transition must be systematically analysed in the context of environment protection.

The European Parliament and the Council endorsed the 7th Environment Action Programme, in accordance with Articles 191–193 of the TFEU, which details European environmental policy (Decision No. 1386/2013). According to this document, waste management and the circular economy are identified as inter-related phenomena. For example, "prosperity and healthy environment stem from an innovative, circular economy where nothing is wasted and where natural resources are managed sustainably", or "barriers facing recycling activities in the Union internal market should be removed and existing prevention, re-use, recycling, recovery and landfill diversion targets reviewed so as to move towards a lifecycle-driven 'circular' economy, with a cascading use of resources and residual waste that is close to zero" (Decision No. 1386/2013).

The European Commission endorsed the Communications *Towards a Circular Economy: A Zero Waste Programme for Europe* (European Commission, 2014) and *Closing the Loop – An EU Action Plan for the Circular Economy* (European Commission, 2015a). As mentioned, the EU legal regulation does not establish an explicit definition of CE, but it reveals itself via the use of the systematic analysis method.

According to these documents, the long-term targets of the CE are: to reduce landfill; and to increase preparation for the reuse and recycling of key waste streams such as municipal waste and packaging waste. These provisions disclose the waste management system as a basic element of the CE, and presuppose the evaluation of the practical realization of waste hierarchy. The concept of the CE envisages the establishment of imperative provisions in legal acts, such as qualitative and quantitative criteria (for example high-quality recycling or boosting the reuse and recycling of municipal waste to a minimum of 70% by 2030) or the simplification and harmonization of definitions. Other elements of the CE involve: designing and innovating; consumption; and functioning markets for secondary materials. Table 1 (below) reveals the content of the elements of the circular economy.

Table 1. Elements of circular economy

Production	Designing
	• Reducing the quantity of materials required to deliver a particular service (lightweighting);
	• Lengthening products' useful life (durability);
	• Creating markets for secondary raw materials (recyclates) based on standards, public procurement, etc.
	Production processes
	• Use of best available techniques for waste management;
	• Implementation of the EU environmental management and audit system;
	• Promoting innovative industrial processes.
Consumption	• Green claims reliability, accuracy, and clarity for preventing and reducing the generation of household waste;
	• Implementation of EU Ecolabel system;
	• Ensuring methodology of Product Environmental Footprint;
	• Prevention of planned obsolescence practices.
Improving the EU legal framework for waste management	• Put into practice the EU waste hierarchy: prevention, preparation for reuse, recycling, energy recovery, disposal;
	• Alignment of definitions;
	• Increase of the target for preparing for reuse and recycling for municipal waste to 65% by 2030;
	• Gradual limitation of the landfill of municipal waste to 10% by 2030;
	• Greater harmonization and simplification of the legal framework on by-products and end-of-waste status.
Boosting the market for secondary raw materials	• Develop quality standards for secondary raw materials;
	• EU regulation on fertilisers;
	• Develop a Raw Materials Information System.

Source: compiled by authors based on European Commission (2014; 2015a)

The European Commission endorsed Proposal for amending Directive 2008/98/EC on waste contains the proposed legislative package for amending the main Directives for waste management, not only Directive 2008/98/EC (European Commission, 2015b). The main objectives of this document (European Commission, 2015b) involve turning waste into a resource and closing the loop in a circular economy. The proposals, which form part of the CE Package, are aimed at addressing the legal obligation to review waste management targets in six different Waste Directives: Directive 2008/98/EC on waste; The Landfilling Directive (1999/31/EC); The Packaging Waste Directive (94/62/EC); The Directives on end-of-life vehicles (2000/53/EC); The Directive (2006/66/EC) on batteries and accumulators (and waste batteries and accumulators); and the Directive on waste electrical and electronic equipment (2012/19/EU). The proposed legislative package also envisages the improvement of targets of waste management, the alignment of definitions, the simplification and streamlining of reporting obligations, the establishment of qualitative and quantitative standards of waste management systems, and the greater harmonization and simplification of the legal framework on by-products and end-of-waste status.

In summary, the legal framework of CE phenomena in the field of waste management covers: TFEU Articles 191–193; the 7th Environment Action Programme; European environment policy (Decision No. 1386/2013); and European Commission communications (2014; 2015a; 2015b), which form part of a Circular Economy Package which includes the six Waste Directives mentioned above.

It is noteworthy that EU environmental law has been in development since the 1970s. Several hundred directives, regulations, and decisions are in force today in this field. Moreover, the effectiveness of EU environmental policy is largely determined not only by its implementation at the national, regional, and local levels, but also worldwide (European Commission, n.d.). The authors state that the CE document package includes the provisions of Agenda 2030. The CE action plan will be instrumental in reaching the Sustainable Development Goals (SDGs) by 2030, in particular Goal 12, i.e. ensuring sustainable consumption and production patterns (United Nations General Assembly's *2030 Agenda for Sustainable Development*).

4. EU waste regulation after amendments, according to the Proposal for Legislative Package (COM (2015) 595 final)

As discussed above, the proposals are aimed at amending six Directives addressing the management of different wastes. The changes to the law documents mentioned are based on Articles 192(1) and 114 of the TFEU:
- Directive (EU) 2018/851 (hereinafter – D 2018/851) of the European Parliament and of the Council of 30 May 2018 amending Directive 2008/98/EC on waste (The Waste Framework Directive, hereinafter – WFD 2008).
- Directive (EU) 2018/850 of the European Parliament and of the Council of 30 May 2018 amending Directive 1999/31/EC on the landfill of waste.
- Directive (EU) 2018/849 of the European Parliament and of the Council of 30 May 2018 amending Directives:
  2000/53/EC on end-of-life vehicles,
  2006/66/EC on batteries and accumulators and waste batteries and accumulators,
  2012/19/EU on waste electrical and electronic equipment.
- Directive (EU) 2018/852 of the European Parliament and of the Council of 30 May 2018 amending Directive 94/62/EC on packaging and packaging waste.

The main objectives of these changes are to improve waste management in the EU, and thereby to contribute to the protection, preservation, and improvement of the quality of the environment, and to the prudent and rational utilisation of natural resources. A systematic assessment of the six Waste Directives to be amended presupposes the need to identify and analyse such basic features.

4.1. Main targets of EU waste regulation

The amended Article 1 of WFD 2008/98/EC, establishes a new provision and divulges the main targets of waste regulation. The subject matter and scope, according to Article 1, lays down measures to protect the environment and human health by preventing or reducing the generation of waste and the adverse impacts of the generation and management of waste, as well as by reducing the overall impacts of resource use and improving the efficiency of such use, both of which are crucial for the transition to a circular economy and for guaranteeing the EU's long-term competitiveness. The content of these provisions is disclosed through the systematic interpretation of other provisions of this document: Article 4 and Article 13. Article 4 reveals the content of waste hierarchy: as a priority order in waste prevention and management legislation and policy. Article 13 establishes the imperative to ensure that waste management is carried out without endangering human health, and without harming the

environment. The CJEU ruled that, whilst Article 13 does not specify the actual content of the measures which must be taken in order to ensure that waste is thus managed without endangering human health and without harming the environment, it is nonetheless true that the article is binding on the Member States as to the objective to be achieved, whilst leaving them a margin of discretion in assessing the need for such measures (*Commission v. Slovenia*, C-153/16). The objects of waste management systems mentioned above are established in all EU Waste Directives such that waste management in the Union should be improved with a view to: protecting, preserving, and improving the quality of the environment; protecting human health; ensuring the prudent, efficient, and rational utilisation of natural resources; and promoting the principles of the circular economy (Directive (EU) 2018/850, Directive (EU) 2018/849).

According to the above, EU waste management regulation includes economic factors (competitiveness, the circular economy, and qualitative standards) and environmental protection (environment, human health, and ensuring the prudent, efficient and rational utilisation of natural resources).

4.2. The harmonization of definitions related to the concept of waste

The circular economy document package emphasizes problematic aspects related to the content of definitions. The problems of definitions concern not only their content, but also involve the development of the waste management system. For example, to ensure the effectiveness of the concepts in practice, quality standards (secondary raw materials), cycles of processes (waste hierarchy), control mechanisms (quantitative and qualitative), and waste classification (hazardous/non-hazardous) are established.

To ensure simplification and the more effective implementation of EU legislation, CE documents propose:
a) to avoid overlaps amongst waste targets and calculation methods;
b) to implement harmonization of definitions (European Commission, 2014; 2015a).
Recitals 9 and 47 of Directive (EU) 2018/851 establish the alignment of the definitions in all Waste Directives and provide for new categories of definitions. Recital 9 specifies that the definitions of non-hazardous waste, municipal waste, construction and demolition waste, food waste, material recovery, backfilling, and extended producer responsibility schemes need to be included in Directive 2008/98/EC so that the scope of these concepts is clarified.

Article 3 of WFD 2008 reveals definitions related to waste management. Analysis of this provision leads to the conclusion that the harmonization of waste definitions will also include the replacement of existing norms. For example, in the definitions of *bio-waste* or *waste management*, the meaning of waste management is extended to include sorting activity.

Recitals of Directives D 2018/852 (amending Directive 94/62/EC on packaging and packaging waste) and D 2018/850 (amending Directive 1999/31/EC on the landfill of waste) highlighting WFD 2008 priority over other Waste Directives, as a legal category, solve the issue of alignment of the definitions: "in order to ensure greater coherence in Union waste law, the definitions in Directive 94/62/EC (or Directive 1999/31/EC) should be aligned, where relevant, with those of Directive 2008/98/EC of the European Parliament and of the Council which is applicable to waste in general". The provisions of amendments to Directive 1999/31/EC and Directive 94/62/EC establish a rule that the definitions of *waste*, *waste management*, *collection*, *separate collection*, *prevention*, *reuse*, *treatment*, *recovery*, *recycling*, *disposal*, and *extended producer responsibility scheme* laid down in Article 3 of WFD 2008 shall apply.

Although the WFD was endorsed in 2008, only 10 years later was a definition of municipal waste established. *Municipal waste* means: (a) mixed waste and separately collected waste from households, including paper and cardboard, glass, metals, plastics, bio-waste, wood, textiles, packaging, waste electrical and electronic equipment, waste batteries and accumulators, and bulky waste, including mattresses and furniture; or (b) mixed waste and separately collected waste from other sources, where such waste is similar in nature and composition to waste from households (WFD 2008). Thus the definition of waste management is revealed, emphasizing: a) the physical and chemical nature of waste (for example bulky waste is similar in nature and composition – i.e. is usually glass, wood, or textile); b) type of waste (mixed waste, bio-waste, bulky waste, waste batteries); c) source (waste from households or waste from other sources); and d) specific items (mattresses, furniture, batteries).

Researchers state that this definition is not accurate because it poses some theoretical questions. For example, what is the meaning of such a definition as *bulky waste*, *mixed waste*, *furniture*, or *waste from other sources* (WFD 2008)? The concept of municipal waste must be interpreted systematically within the concept of waste. It should be noted that the concept of waste has remained unchanged: *waste* means any substance or object which the holder discards or intends or is required to discard (WFD 2008). To reveal a clear meaning of waste is not simple. Firstly, it is necessary to assess what is not waste – cases that shall be excluded from the scope of WFD 2008 (Article 2). Secondly, to identify *end-of-waste* status (Article 6) or if a substance or object is considered not to be waste, but to be a *by-product* if the conditions mentioned in Article 5 are met.

The concept of waste is widely discussed among researchers and in the decisions of the CJEU. Some authors describe waste as objects that have an economic value, which may manifest in positive or negative aspects. L. Kramer states that "wastes are physical objects and as such are capable of being traded between Member States, and a buyer might have an interest in acquiring waste which has an economic value" (2012, pp. 76–77.). M. Grosz perceives "waste as a material or an assembly of materials with negative value" (2011, p. 8). Others note that waste contains the same materials as are found in useful products; it only differs from useful production by its lack of value (White, Franke, & Hidle, 1999).

Some authors highlight classification of criteria which divulge the concept of waste. Waste takes on various material forms and can feature any of the three classic aggregate phases: it may occur as a solid material, in liquid form, or even as a gaseous emission (Grosz, 2011). Sources of wastes are as follows: domestic wastes; commercial wastes; ashes; animal wastes; biomedical wastes; construction wastes; industrial solid wastes; sewers; biodegradable wastes; non-biodegradable wastes; and hazardous wastes (Demirbas, 2011). Authors on this topic additionally highlight such criteria as inert waste, processed waste, and unprocessed waste.

It should be noted that there exists another concept of waste – *waste* as an action. This requires a discussion on the content of waste based on the concept of *discarding*: the holder discards, or intends, or is required to discard an object (WFD 2008). This legal definition resembles the everyday understanding of waste – as something that we discard or throw away into the rubbish bin, using three alternatives: (1) which the holder discards; or (2) intends; or (3) is required to *discard* (Fisher, Lange, & Scotford, 2019, p. 521). However, as mentioned, no definition of the term discard is given in the WFD 2008. This situation creates a broad definition of *waste* and a lack of clarity as to its precise meaning, which continues to provide difficulties in national implementation of the WFD 2008 and its subsequent daughter directives (Davies, 2017, pp. 226–228).

The CJEU, ruled to interpret the concept of waste widely, and the meaning *waste* is to be inferred primarily from the holder's actions and the meaning of the term *discard* (*Openbaar Ministerie v. Tronex BV*, Case C-624/17; *Shell Nederland Verkoopmaatschappij BV and Belgian Shell NV,* Case C-241/12). The term *discard* covers both

disposal and *recovery* of a substance or object (*Inter-Environnement Wallonie ASBL v. Région wallonne*, Case C-129/96).

The Court also indicated that the existence of waste within the meaning of WFD 2008, must be determined in the light of all of the circumstances, and must be held to the aim of that directive and ensure that its effectiveness is not undermined. For example, an object or substance in question is not or is no longer of any use to its holder (constituting a burden and possessing the criterion to discard); or there is a degree of probability that goods, a substance, or a product will be reused without a prior processing operation (constituting a criterion to reuse, and not to discard; *Commission v. Italy*, Case C-263/05).

Based on the analysed data, the authors argue that the EU legal regulation develops the concept of definitions regarding the waste. It is possible to identify the classification of waste types and the systematic improvement (harmonization) of the content of definitions of waste. On the other hand, the concept of waste needs to be improved, which must meet the requirements of the waste hierarchy. Analysis of the CJEU judgments revealed a tendency whereby the meaning of the concept of waste is discussed in the context of waste hierarchy, for example the term *discard* manifesting in the stages of recovery or disposal. The authors agree with the provision that "the legal definition of waste overlooks the context of waste, fails to consider the interests of the waste user as opposed to the waste holder, and aims to control the impacts of careless discarding rather than stimulating careful discarding" (Ewijk & Stegemann, 2020).

4.3. Waste hierarchy

The waste hierarchy establishes a priority order for prevention, preparation for reuse, recycling, and energy recovery through disposal, such as landfilling (European Commission, 2015a). Article 4 of WFD 2008 establishes the main elements (steps) of waste hierarchy: (a) prevention; (b) preparing for reuse; (c) recycling; (d) other recovery, e.g. energy recovery; and (e) disposal. According to Article 4 of Directive 2018/851, the following paragraph is added: "3. Member States shall make use of economic instruments and other measures to provide incentives for the application of the waste hierarchy, such as those indicated in Annex IVa or other appropriate instruments and measures". Annex IV divulges examples of economic instruments and other measures to provide incentives for the application of the waste hierarchy. These instruments include: charges and restrictions for using landfill and the incineration of waste, which incentivise waste prevention and recycling whilst keeping landfill the least preferred waste management option; fiscal incentives for the donation of products, in particular food; and the phasing out of subsidies which are not consistent with the waste hierarchy. Such measures are established in order to contribute to achieving the objectives laid down in Article 1 of the WFD 2008.

Waste hierarchy manifests as an obligatory imperative to Member States' waste management systems. Member states must undertake measures to prevent waste generation and ensure that waste undergoes preparation for reuse, recycling, or other recovery operations, and monitor and assess the implementation of waste prevention measures. For that purpose, they must use appropriate qualitative or quantitative indicators and targets, notably on the quantity of waste that is generated (WFD 2008).

The CJEU ruled that waste hierarchy must be revealed in the light of WFD 2008 Article 13: "Member States take the necessary measures to ensure that waste management is carried out without endangering human health and without harming the environment, in particular without risk to water, air, soil, plants or animals" (*"Verdi Ambiente e Società – Aps Onlus" (VAS) and "Movimento Legge Rifiuti Zero per l'Economia Circolare" Aps v. Presidente del Consiglio dei Ministri and Others*, Case C-305/18). In that regard, the Court has already ruled that,

whilst Article 13 does not specify the actual content of the measures which must be undertaken in order to ensure that waste is managed without endangering human health and without harming the environment, it is nonetheless true that that article is binding on the Member States as to the objective to be achieved, whilst leaving them a margin of discretion in assessing the need for such measures (*Commission v. Slovenia*, Case C-153/16).

Is the waste hierarchy mechanism enshrined in all of the Waste Directives? As mentioned above, the main target of the CE Documents Package is the alignment of definitions, and the greater harmonization and simplification of the legal framework of waste management. Recital 6 of Directive D 2018/849 (amending Directives 2000/53/EC, 2006/66/EC, 2012/19/EU) reveals: "The waste hierarchy laid down in WFD 2008 applies as an order of priority in the Union waste prevention and management legislation. When complying with the objectives of this Directive, Member States should take the necessary measures to take the order of priorities of the waste hierarchy into account and ensure the practical implementation of those priorities". Article 6 of Directive 2000/53/EC is amended as follows: "Member States shall take the necessary measures to ensure that all end-of-life vehicles are stored (even temporarily) and treated in accordance with the waste hierarchy and the general requirements laid down in Article 4 of WFD 2008". Article 22a, inserted into Directive 2006/66/EC, divulges incentives for the application of the waste hierarchy: "in order to contribute to the objectives laid down in this Directive, Member States may make use of economic instruments and other measures to provide incentives for the application of the waste hierarchy, such as those indicated in Annex IVa to the WFD 2008". The same principle is laid down in the provisions of Article 16a, inserted into amended Directive 2012/19/EU. The replaced article of Directive 94/62/EC on packaging and packaging waste stated that "In line with the waste hierarchy laid down in Article 4 of WFD 2008, Member States shall take measures to encourage the increase in the share of reusable packaging placed on the market and of systems to reuse packaging in an environmentally sound manner". With a view to supporting the Union's transition to a circular economy and meeting the requirements of WFD 2008 of the European Parliament and of the Council (1), and in particular Articles 4 and 12 thereof, the aim of this Directive is to ensure a progressive reduction in the landfilling of waste (Directive 1999/31/EC on the landfill of waste).

Based on the provisions mentioned, the authors argue that waste hierarchy, according to the CE documents package, is established as an imperative provision of EU waste regulation, including all key waste streams. This disclosure exists with the provision that waste hierarchy exists as *Lex specialis* (the doctrine states that if two laws govern the same factual situation, a law governing a specific subject matter (*lex specialis*) overrides a law governing only general matters (*lex generalis*). The content of imperative meaning consists of waste hierarchy stages, and the monitoring and assessment of qualitative or quantitative indicators and targets. Waste hierarchy manifests as a systematic phenomenon, which includes not only its obligatory nature, but also its status as an economic instrument to provide incentives for the application of the waste hierarchy.

5. Conclusions

The implementation of the circular economy concept of the EU had an important impact on the legal regulation of waste in the Union. Six directives have been amended: Waste Framework Directive 2008/98/EC; Directive 1999/31/EC on the landfill of waste; Directives 2000/53/EC on end-of-life vehicles; 2006/66/EC on batteries and accumulators and waste batteries and accumulators; 2012/19/EU on waste electrical and electronic equipment; and Directive 94/62/EC on packaging and packaging waste. The systematization of Waste Directives presupposes a conclusion that Waste Framework Directive 2008/98/EC discloses waste regulation as a fundamental Directive in the EU. The provisions of amended Waste Directives established references or priorities to Waste Framework Directive 2008/98/EC, interpreting the principles, definitions, or main targets of waste management. All disputes concerning the definition of the Directives should be guided by the Waste Framework Directive 2008/98/EC

The authors conclude that the main elements of change in EU waste regulation must be the systematization of Waste Directives, the alignment and improvement of definitions related to the concept of waste, and ensuring the implementation of waste hierarchy and the targets of the waste management system. The waste hierarchy establishes a priority system within waste management, covering all types of waste. Waste hierarchy as legal imperative is established in all six amended Waste Directives, and manifests as a systematic phenomenon which includes imperative waste hierarchy stages, the monitoring and assessment of qualitative or quantitative indicators, and targets and economic instruments to provide incentives for the application of the waste hierarchy.

The new version of the Waste Framework Directive 2008/98/EC established new definitions (municipal waste) related to the concept of waste, as well as improving existing ones (waste management). It should be noted that the basic definition of waste remains unchanged. Analysis of the CJEU jurisprudence revealed arguments that waste definition exists as a problematic legal issue. The authors believe that the concept of waste needs to be improved in the light of the waste hierarchy, circular economy, and the CJEU jurisprudence. The authors conclude that the Directives should clearly and unambiguously define the concept of the circular economy.

STRIKING A HEALTHIER BALANCE BETWEEN AIR PASSENGER RIGHTS AND AIR CARRIERS' VITAL INTERESTS IN THE LIGHT OF COVID-19

Regina Valutytė

Mykolas Romeris University, Ateities Str. 20, Vilnius, Lithuania

E-mail: r.valutyte@mruni.eu

Abstract. Regulation 261/2004 is a directly applicable EU legal act establishing common rules on compensation and assistance to passengers in the event of denied boarding, flight cancellations, or long delays of flights. The 'extraordinary circumstances defence' is expressly provided by Regulation 261/2004, in favour of air carriers to justify the refusal to pay compensation to passengers. However, the concept of extraordinary circumstances is far from being clear, and continuously raises questions of interpretation. Covid-19, as an extraordinary circumstance, brings previous discussions on the weaknesses of Regulation 261/2004 back to light, particularly regarding the extent of air passengers' rights embedded in Regulation 261/2004. Accordingly, this research aims to discuss whether the Regulation ensures the proper balance between the interests of passengers and air carriers in emergencies like Covid-19. Possible developments of existing regulation, allowing for the striking of a better balance between the interests of the aviation industry and consumer rights in situations like Covid-19, and thus ensuring the sustainability of the aviation market, are discussed. The discussion focuses on the regulation surrounding vouchers as an alternative method of reimbursement in case of the cancellation of a flight, and the extent of the right to offer assistance and care to passengers awaiting another flight.

Keywords: aviation; air passenger rights; extraordinary circumstances; Regulation 261/2004; Covid-19

1. Introduction

On 30 January 2020, the United Nations World Health Organization (hereinafter – WHO) declared the Covid-19 outbreak a 'public health emergency of international concern' (WHO, 2020a) which, on 11 March 2020, was characterised as a pandemic (WHO, 2020c). Efforts to tackle the pandemic's spread resulted in the imposition of

travel restrictions and the suspension of flights. The United Nations World Tourism Organization reports that as of 31 May 2020, 100% of all destinations worldwide had some forms of Covid-19-related travel restrictions. As of 18 May 2020, 75% of the destinations continued to have their borders completely closed for international tourism. In 37% of all cases, travel restrictions have been in place for 10 weeks, while 24% of global destinations had restrictions in place for 14 weeks or more (United Nations World Tourism Organization, 2020).

As the Great Depression did in its time, the Great Lockdown continues to have a tremendous economic impact (International Monetary Fund, 2020), with the aviation industry hit the hardest among other sectors. The world's total passenger traffic is forecast to decrease drastically. For instance, the International Civil Aviation Organization (hereinafter – ICAO) indicates that for the full year of 2020, the impact of Covid-19 would imply an overall decrease ranging from 46% to 51% of seats offered by airlines. Concerning passengers, it foresees an overall decrease of 2.605 to 2.894 million of passengers (predictions based on the traffic data as of 19 August 2020; International Civil Aviation Organization, 2020). As a result, the pandemic has had a tremendous impact on airlines' financial situations, and the ICAO (2020) estimates approximately USD 214 billion in passenger revenue loss from January to July 2020. The pandemic has created an 'unprecedented disruption' (Partington & Partridge, 2020) in aviation, and many airlines are relying on governmental financial assistance to stay afloat. The International Air Transport Association (hereinafter – IATA) does not expect any recovery from this until 2023 (International Air Transport Association, 2020).

Alongside this, the European Commission observes that the economic impact of the crisis has also affected travellers, since their income has reduced as a result of the curtailment of economic activities (European Commission, 2020a, para. 13). Regulation (EC) No. 261/2004 of the European Parliament and of the Council of 11 February 2004, *establishing common rules on compensation and assistance to passengers in the event of denied boarding and of cancellation or long delay of flights, repealing Regulation (EEC) No 295/91* (hereinafter – Regulation 261/2004), establishes the obligations of air carriers to offer, depending on the situation, reimbursement (refund), re-routing at the earliest opportunity, or re-routing at a later date at the passenger's convenience, compensation, care, and assistance to air passengers. The Regulation foresees the concept of extraordinary circumstances (arguably such as Covid-19), where the air carrier is exempted from the obligation to pay compensation. However, no differentiation of extraordinary circumstances based on their severity is envisaged in terms of air passenger protection. Covid-19 has brought back the discussion of the imbalance between the interests of passengers and air carries embedded in the Regulation, which was last provoked by the eruption of the Icelandic volcano Eyjafjallajökull, and was followed by scholarly reflection (Abeyratne, 2010; Correia, 2014). In the case of the pandemic, numerous cancellations of flights have led to an unsustainable cash-flow and revenue situation for air carriers (European Commission, 2020a, para. 14), since financially struggling airlines face numerous refund claims instead of travellers accepting vouchers for future flights (a relatively new practice developed by air carriers during Covid-19). Therefore, the question of the feasibility of introducing vouchers as an alternative at the discretion of the air carrier in such circumstances as Covid-19 has become of particular relevance.

Accordingly, the purpose of this article is to discuss whether Regulation 261/2004 ensures a proper balance between the interests of passengers and air carriers in emergencies such as Covid-19. To this end, this analysis will focus on the extent of the rights of passengers whose flights are cancelled or delayed in exceptional circumstances which have a devastating economic impact on air carriers. Based on the textual and teleological interpretation of the Regulation 261/2004, as well as the practice of the Court of Justice of the European Union (hereinafter – CJEU), this article will reconstruct the concept of extraordinary circumstances under the Regulation in relation to a specific context of Covid-19. Subsequently it will discuss the conditions activating air carriers' obligations towards air passengers in the cases of cancellation and delays. It will also consider the possible

development of existing Regulation that would allow the striking of a better balance between the interests of the aviation industry and consumer rights in situations such as Covid-19, and thus ensure the sustainability of the aviation market.

2. Covid-19 as an extraordinary circumstance

Regulation 261/2004 does not define *extraordinary circumstances*; however, Recital 14 of the preamble to the Regulation hints at some relevant features of the concept. Therein, the legislator refers to the 'circumstances which could not have been avoided even if all reasonable measures had been taken', an expression that, excluding the preamble, is mentioned three times in the main text of the Regulation (Recital 12, Recital 15, and Article 5). Since the concept lacks clarity, it was inevitable that the circumstances in which this defence is available would become a matter of dispute (Balfour, 2009, p. 225).

Having the exclusive competence to provide binding interpretations to the unclear provisions of EU law, the CJEU has continuously assisted the aviation industry and passengers with the interpretation of the concept of extraordinary circumstances. As Pierallini aptly phrased it, the Court 'has innovated the interpretation of Regulation 261/2004 with regards to compensation for flights' (2013, p. 120). The case of *Friederike Wallentin-Hermann v. Alitalia* (2008) is one of the best examples of the CJEU's active role in forming the practice of the implementation of the Regulation in using the extraordinary circumstances defence to avoid liability against passengers.

In *Friederike Wallentin-Hermann v. Alitalia*, the CJEU confirms two key aspects relevant to the concept of extraordinary circumstances embedded in the Regulation. Firstly, the statement in Recital 14 of the Regulation's preamble contains no list of extraordinary circumstances themselves, but only the events that may produce such circumstances (*Friederike Wallentin-Hermann v. Alitalia*, 2008, para. 21). Secondly, the Regulation does not provide an exhaustive list of these events either. The examples mentioned in Recital 14 (cases of political instability, meteorological conditions incompatible with the operation of the flight concerned, security risks, unexpected flight safety shortcomings, and strikes that affect the operation of an air carrier) are regarded as events that have great potential but may not necessarily produce exceptional circumstances (*Friederike Wallentin-Hermann v. Alitalia*, 2008, para. 22). Relying on this interpretation of Recital 14, the Court establishes two cumulative conditions for characterizing an event as extraordinary: 1) the event by nature or origin must not be inherent in the normal exercise of the activity of the air carrier concerned; and 2) the event must be beyond the actual control of that carrier on account of its nature or origin (*Friederike Wallentin-Hermann v. Alitalia*, 2008, para. 23).

The CJEU has remained consistent and clear in developing its case-law regarding the air passengers' rights. Consumer protection lies at the heart of the Regulation; therefore, any terms that may restrict air passengers' rights must be interpreted strictly (*Friederike Wallentin-Hermann v. Alitalia*, 2008, para. 17). In this context, as Prassl (2016, p. 138) accurately concludes, the extraordinary circumstances defence must be interpreted narrowly. As demonstrated below, the well-established case-law shows that the Court strictly adheres to this rule while interpreting whether certain events qualify as extraordinary circumstances.

Among the circumstances characterized as extraordinary, the CJEU has accepted: some technical problems (*Corina van der Lans v. Koninklijke Luchtvaart Maatschappij NV*, 2015, para. 38); a collision between an aircraft and a bird (Peskova, 2017, para. 24); the behaviour of unruly passengers (*LE v. Transportes Aéreos Portugueses*

SA, 2020, para. 48); the consequences of a volcanic eruption (*Denise McDonagh v. Ryanair Ltd*, 2013, para. 24); and damage caused by an unexpected object on the airport runway (*Germanwings GmbH v. Wolfgang Pauels*, 2019, para. 26). On the contrary, technical problems such as: a collision with mobile stairs (*Sandy Siewert and Others v. Condor Flugdienst GmbH,* 2014, para. 19); failure resulting from the inadequate maintenance of an aircraft (*A and Others v. Finnair Oyj*, 2020, para. 42); and a wildcat strike among the staff of the air carrier (*Helga Krüsemann and Others v. TUIfly GmbH*, 2018, 42) did not amount to extraordinary circumstances.

In *Friederike Wallentin-Hermann v. Alitalia* (2008, para. 25), the CJEU suggested that technical problems that came to light during aircraft maintenance or are caused by the failure to maintain an aircraft could not be regarded as extraordinary circumstances, since such a breakdown remains intrinsically linked to the operating system of the aircraft. In *Corina van der Lans v. Koninklijke Luchtvaart Maatschappij NV* (2015, para. 14, 18), as was expected due to the lack of clarity in the Court's ruling in *Friederike Wallentin-Hermann v. Alitalia* (Croon, 2015, p. 335), the Luxembourg court did not accept KLM's arguments that spontaneous technical problems, as opposed to technical issues discovered during routine maintenance checks of the aircraft, constitute an extraordinary circumstance. In line with the principle of a strict interpretation of consumer rights limitations, the Court elaborated in para. 38 and 40 that technical problems might constitute extraordinary circumstances if 'not only that specific aircraft but also others in the fleet had been affected by a hidden manufacturing defect affecting the safety of flights'.

Contrary to the suggestions of Advocate General Bots (2016, para. 42), a collision between an aircraft and a bird, as well as any damage caused by that collision, was also recognized as 'out of the ordinary' and 'out of control' in *Marcela Pešková and Jiří Peška v. Travel Service a.s.* (2017, para. 24). The Court classified such a collision as extraordinary circumstances, clearly linking its finding with the non-existence of the 'intrinsic linkage' of the event to the operating system of the aircraft (2017, para. 24).

In the most recent case of *LE v. Transportes Aéreos Portugueses SA*, the Court accepted that 'unruly behaviour of such gravity as to justify the pilot in command diverting the flight concerned is not inherent in the normal exercise of the activity of the operating air carrier concerned' (2020, para. 41). The Court established the standards of a responsible passenger, who normally complies with all orders issued by the commander to ensure safety on board and ensures that they do not themselves jeopardize the proper performance of the contract of carriage between themselves and the operating air carrier concerned (2020, para. 42). As to the second condition, the CJEU gave instructions for assessing if the behaviour of such a passenger is out of the control of the air carrier concerned. In such cases, one has to ascertain the contribution of the air carrier to the occurrence of the unruly behaviour of the passenger, or the possibility to anticipate unruly behaviour and take appropriate measures at a time when it was possible to do so without any significant consequence for the operation of the flight concerned based on the warning signs of such behaviour (2020, para. 45).

In *Sandy Siewert and Others v. Condor Flugdienst GmbH* (2014), the CJEU noted that mobile stairs or gangways could be regarded as indispensable to air passenger transport, and air carriers were regularly faced with situations arising from the use of such equipment. The use of equipment that enables passengers to enter or leave the aircraft, in the Court's view, falls within normal airport services (2014, para. 19), and thus may not be regarded as an extraordinary circumstance. Likewise, in *Helga Krüsemann and Others v. TUIfly GmbH*, the Court did not accept that a wildcat strike among the staff of the air carrier might constitute extraordinary circumstances, since the restructuring and reorganization of undertakings, which the wildcat strike followed in *TUIfly* case, are part of the normal management of legal entities (2018, para. 40, 42).

The case-law, as mentioned earlier, demonstrates that the decisive factor governing a certain circumstance's characterization as extraordinary is its attribution to the factors lacking intrinsic linkage with the operating system of the aircraft or the usual management of airlines. Whether the factor is internal or external to the aircraft or airlines is not an important factor for this determination.

As regards the Covid-19 pandemic, the European Commission considers that the measures intended to contain the Covid-19 pandemic taken by public authorities are by their nature and origin not inherent in the normal exercise of the activity of carriers, and are outside of their actual control (European Commission, 2020a, para. 3.4). To justify this statement, it is necessary to discuss if a spreading disease meets the above-mentioned cumulative criteria.

Pandemic, epidemic, endemic, and outbreak are often misused terms (Dietz & Black, 2012, p. xxvii; Grennan, 2019). These terms are commonly used to describe infections; however, they are primarily based on how many cases of a condition there are compared with the expected number of cases over a given time, and the geographical spreading of the cases (Grennan, 2019). Diseases that are constantly present in a population within a particular geographic region are called endemic diseases **(Grennan, 2019).** For example, malaria is endemic to some regions of the Amazon Brazil, in South and Central America, Africa, and Asia; dengue is common in the Caribbean, Central and South America, Southeast Asia, and the Pacific Islands (Felman, 2020). The terms *outbreak* and *epidemic* are quite often used similarly, and are defined as the occurrence of more cases of disease than expected in a given area or among a specific group of people over a particular period of time (Parthasarathy, 2013, p. 444). An outbreak usually indicates less intensity, and the differentiation is based on the number of cases per number of inhabitants, the percentage of overall deaths causes by the disease, etc. (Parthasarathy, 2013, p. 444). Examples of epidemics include the Zika virus, starting in Brazil in 2014 and spreading to most of Latin America and the Caribbean; or the 2014–2016 Ebola outbreak in West Africa (Grennan, 2019). The WHO defines a pandemic as the worldwide spread of a new disease (WHO, 2010). While an epidemic remains limited to one city, region, or country, a pandemic spreads beyond national borders and possibly worldwide (Felman, 2020). Rare examples of pandemics include the Spanish Flu of 1918, which killed roughly 50 million people worldwide, and the H1N1 virus in 2009 (Felman, 2020).

When Covid-19, which originated in Wuhan, China, was characterized as a pandemic, the disease was widely spread across the world – there were more than 118,000 cases in 114 countries and 4,291 deaths. As of 22 August 2020, 213 countries and territories around the world have reported a total of 23,144,577 confirmed cases of Covid-19 and 803,634 deaths (Worldometer, 2020). Considering the characteristics mentioned above, the Covid-19 pandemic neither by nature nor origin is inherent in the normal exercise of the activity of the air carrier concerned. Owing to its nature or origin this event clearly goes beyond the actual control of air carriers.

However, one must observe that the majority of pandemics or epidemics satisfy the cumulative conditions established in the case-law of the CJEU, since airlines are not linked with their appearance and have no control over them. Abeyratne (2012, p. 115) pays attention to the rule that the extraordinary circumstances defence is not an absolute one; it must be accompanied by the fact that the extraordinary circumstances 'could not have been avoided although the airlines took all reasonable measures. Thus, proving two cumulative conditions for the event to be classified as extraordinary is not enough for the purpose of avoiding liability to pay compensation to passengers. As the European Commission accurately points out, in order to be exempt from the payment of compensation the carrier must simultaneously prove two additional conditions: 1) the causal link between the extraordinary circumstances and the delay or the cancellation; and 2) the fact of inability to avoid the delay or cancellation in spite of all reasonable measures taken (European Commission, 2016, para. 5.1).

As to the causal link, not all pandemics or epidemics lead to a lockdown or restrictions on air transportation. For example, in early 2015 an outbreak of Zika fever in Brazil, caused by the Zika virus, spread to other parts of South and North America, several islands in the Pacific, and Southeast Asia (Sikka et al., 2016). Since the virus was transmitted predominately via mosquito vectors and, possibly, other modes including blood transfusion and sexual intercourse (Sikka et al., 2016), the WHO did not recommend any general restrictions on travel to and from the countries, areas, and/or territories of Zika virus transmission (WHO, 2016). Contrarily, the virus that causes Covid-19 spreads very easily and sustainably between people and from contact with contaminated objects and surfaces, and is particularly dangerous to older people and people with some pre-existing health conditions. Despite the WHO consistently recommending against restrictions on international travel (WHO, 2020b), almost every country in the world implemented some type of mandatory restrictions contrary to the WHO advice (von Tigerstrom & Wilson, 2020).

Therefore, the main reasons for the cancellation of the flights were the border closures of the countries, as implicitly observed by the European Commission in its guidelines (European Commission, 2020a, para. 3.4). These restrictions left no place to manoeuvre for the airlines, and so were the main reason for the cancellation of the flights. Since the CJEU requires a direct causal link between the extraordinary circumstances and the cancellation of the flight (*LE v. Transportes Aéreos Portugueses SA,* 2020, para. 54), one might wonder whether the direct causality may be established only between national bans on international travel and the cancellation of a flight, rather than between cancellations and Covid-19 itself, since despite the ongoing pandemic some airlines have continued to transport passengers where there are no restrictions to air transportation imposed as recommended by the WHO. In the author's view, both factors (Covid-19 itself and national legal measures) are eligible for establishing a direct causal link. State legal measures of a general nature (non-specific to particular air carriers), in particular banning air transportation activities, are widely accepted as extraordinary circumstances due to airlines' inability to impact them. Therefore, airlines may rely on the national legal measures as a direct reason for the cancellation of a flight. On the other hand, airlines may opt not to operate a flight due to the occurrence of Covid-19 itself, even if there are no travel restrictions. As mentioned above, Covid-19 is a pandemic threatening public health worldwide, the virus causing the disease is being transmitted via contaminated surfaces and easily spreading from person to person. Therefore, the virus may pose a risk not only to passengers but also to airline staff, and as such if an airline decides to cancel a flight in the absence of flight bans to a particular country, there still exists a direct causal link between Covid-19 and the cancellation.

The other condition to satisfy exemption from the responsibility to pay compensation is the obligation to take all reasonable measures to avoid extraordinary circumstances. In explaining the scope and extent of reasonable measures, the Court placed emphasis on the balance between the interests of air passengers and air carriers in a number of cases. The Court 'established an individualized and flexible concept of 'reasonable measures', leaving to the national court the task of assessing whether, in the circumstances of the particular case, the air carrier could be regarded as having taken measures appropriate to the situation' (*Andrejs Eglītis and Edvards Ratnieks v. Latvijas Republikas Ekonomikas ministrija*, 2011, para. 30; *Marcela Pešková and Jiří Peška v. Travel Service a.s.*, 2017, para. 30). The CJEU clarified that in order to meet this condition, an air carrier must demonstrate that 'even if it had deployed all its resources in terms of staff or equipment and the financial means at its disposal, it would clearly not have been able, unless it had made intolerable sacrifices in the light of the capacities of its undertaking at the relevant time, to prevent the extraordinary circumstances with which it was confronted from leading to the cancellation of the flight or its delay equal to or in excess of three hours in arrival' (*Christopher Sturgeon and Others*, 2009, para. 61; *Andrejs Eglītis and Edvards Ratnieks v. Latvijas Republikas Ekonomikas ministrija*, 2011,

para. 25; *Germanwings GmbH v. Wolfgang Pauels*, 2019, para. 19; *LE v. Transportes Aéreos Portugueses SA,* 2020, para. 36).

In *Marcela Pešková and Jiří Peška v. Travel Service a.s.* (2017), for example, the Court was not persuaded that the airlines took all of the reasonable measures to avoid the extraordinary circumstances. The CJEU observed that the air carriers were free to use the experts of their choice to carry out the checks necessitated by a collision with a bird. However, when a check had already been carried out after such a collision by an expert authorised to do so under the applicable rules, a second check inevitably leading to a delay equal to or in excess of three hours to the arrival of the flight was not reasonable (2017, para. 37).

The case-law of the CJEU demonstrates that despite the gravity of the situation, which is characterized as extraordinary, air carriers must ensure that all reasonable measures in their hands are deployed to avoid the circumstances and thus mitigate their negative effect. Regarding Covid-19, it is clear that airlines can do nothing to avoid the pandemic, however, they can mitigate the negative impact on passengers by applying the rule established in Article 5(c)(i) of the Regulation which *de jure* exempts them from their liability to pay damages. Under Article 5(c)(i), air carries do not have to pay compensation if they inform the passengers of the cancellation at least two weeks before the scheduled time of departure. Considering that the current case-law of the CJEU is strictly oriented towards consumer protection, the assessment of the measures deployed to make use of this possibility may be a relevant factor for deciding if the air carrier has the obligation to pay compensation, in particular in the situations where the air carrier knows well in advance that the flight will be cancelled due to the closure of the airspace.

3. The extent of passenger rights in the case of Covid-19

Independently from the cause of the cancellation, Article 5 of Regulation 261/204 obliges the operating air carrier to offer the passengers the following choices: reimbursement (refund), re-routing at the earliest opportunity, or re-routing at a later date at the passenger's convenience. The European Commission, in its Interpretative Guidelines, guides passengers on the implementation of the above-mentioned rights (European Commission, 2016). If the outbound flight and the return flight are part of the same booking, even if operated by different air carriers, passengers should be offered two options if the outbound flight is cancelled: to be reimbursed for the whole ticket (i.e. both flights), or to be re-routed onto another flight for the outbound flight (European Commission, 2016, Point 4.2). As regards re-routing, 'the earliest opportunity' may imply considerable delay under the circumstances of the Covid-19 outbreak, and the same may apply to the availability of concrete information on such an opportunity given the high level of uncertainty affecting air travel. However, at any rate passengers should be informed about the delays and uncertainties linked to them choosing a re-routing instead of reimbursement. Should a passenger nonetheless choose re-routing at the earliest opportunity, the carrier should be considered as having fulfilled its information obligation towards the passenger if it communicated the flight available for re-routing on its own initiative, as soon as possible, and in good time (European Commission, 2020a, para. 3.2).

Regarding the form of the reimbursement, it is important to mention that Article 7(3) lists possible forms of reimbursement. Travel vouchers are explicitly mentioned among those forms, however, as the European Commission accurately mentions in its guidelines, the offer of a voucher by the airlines cannot affect the passenger's right instead to opt for cash by electronic bank transfer, bank orders, or bank cheques (European Commission, 2020a, para. 2.2.).

The rationale behind this regulation is clear from the perspective of a passenger. First of all, the trip on the other date may lose its purpose to a particular passenger or limit their opportunities to choose a cheaper option in the market when buying a ticket in the future. Additionally, a situation such as Covid-19 creates the risk of an air carrier becoming insolvent, which could eliminate the passenger's possibilities to make use of a voucher. On the other hand, as the European Commission aptly observes in its recommendation on vouchers offered to passengers and travellers as an alternative to reimbursement for cancelled package travel and transport services in the context of the Covid-19 pandemic (2020a, Recital 14), 'if organisers or carriers become insolvent, there is a risk that many travellers and passengers would not receive any refund at all, as their claims against organisers and carriers are not protected'. Thus, it is in the interest of the better protection of passengers as a whole to ease the liquidity problems of carriers and make sure that once the sky is open again, the air transportation business is viable and competitive.

The question of introducing the option of a voucher as an alternative at the discretion of the air carrier rather than the passenger in exceptional circumstances that threaten the liquidity of air carriers has not been discussed in the latest Proposal for a Regulation of the European Parliament and of the Council amending Regulation 261/2004 (Council of European Union, 2020). Nor was it reviewed in the Proposal for a Regulation of the European Parliament and of the Council amending Regulation 261/2004 (European Commission, 2013), which was widely discussed by different stakeholders without reaching a compromise in the end. The European Commission already aims to encourage the acceptance of vouchers by guiding air carriers towards implementing a set of recommended characteristics to make vouchers an attractive and reliable alternative to monetary reimbursement. Thus, the introduction of a voucher as an equal alternative form of reimbursement upon the choice of the carrier in certain circumstances, combined with all the guarantees afforded to this form of reimbursement, may be worth discussing in seeking to strike a better balance between the sustainability of business and the protection of air passengers as a whole.

4. Care in extraordinary circumstances

Articles 8 and 9 of Regulation 261/2004 include the right of passengers to receive information, meals and refreshments, telephone calls, and accommodation if necessary, as well as transportation to the place of accommodation and back. The right to care begins when a passenger chooses re-routing at a later date at the passenger's convenience (Article 5(1)(b) in conjunction with Article 8(1)(c); European Commission, 2020a, para. 3.3.). Accordingly, airlines do not have the obligation to assist the passengers in the way described in Article 9 if a passenger opts for reimbursement of the full cost of the ticket.

Article 9 seeks that the needs of passengers waiting for their return flight or re-routing are adequately addressed (European Commission, 2020a, para. 3.3.). The European Commission observes that the extent of adequate care is assessed on a case-by-case basis, taking into consideration the needs of air passengers in the circumstances and the principle of proportionality according to the waiting time (European Commission, 2020a, para. 4.3.2.).

The European Commission accepts that the Regulation has no provision allowing airlines to decline to offer care when the cancellation of a flight is caused by circumstances which could not have been avoided even if all reasonable measures had been taken (European Commission, 2020a, para. 4.3.2.). The closure of part of European airspace as a result of the eruption of the Eyjafjallajökull volcano in 2010 provoked the question of the extent of care in the circumstances where, depending on their origin and the scale of the situation, passengers waited for their return flights for weeks.

In this regard, Jones observes that the idea of 'super extraordinary circumstances' was dismissed based on the argument that a full range of extraordinary circumstances had been intended to fall under the term (2016, p. 232). Indeed, the CJEU explained that there was no separate category of 'particularly extraordinary' events, which would exempt the air carrier from offering care to the passengers (*Denise McDonagh v. Ryanair Ltd*, 2013, para. 30). Wijngaart argues that the way the CJEU interprets the extraordinary defence is not in line with the legislator's intent behind the Regulation, and is pessimistic about changing the case-law in the future with this argument (2016, p. 62). In the author's view, the present practice of the Court's may be modified if the relevant changes are introduced in the Regulation text. The CJEU does not ban the possibility of differentiating between extraordinary circumstances based on their gravity in general. Since efforts to revise the Regulation have recently been heightened, there is a chance to revisit the concept of extraordinary circumstances by establishing a special regime for super-extraordinary circumstance (e.g., epidemics, pandemics).

The situation materializing due to Covid-19 has again brought to light the weaknesses of the Regulation. Although the European Commission urges air carries to inform passengers of all the risks associated with the choice of re-routing instead of reimbursement, it does not release them from the obligation of providing care and assistance to passengers waiting at their destination for an undetermined period of time before they can return home, even if they unilaterally assumed the risk of facing an airspace closure. Pinpointing the legislator's choice, the CJEU takes the consumer-oriented approach by stating in *Denise McDonagh v. Ryanair Ltd* that there is no limitation, 'whether temporal or monetary, of the obligation to provide care to passengers in extraordinary circumstances' (2013, para. 40) for the whole period during which the passengers concerned must await their re-routing (para. 41). The Court emphasizes that the importance of the objective of consumer protection, which includes the protection of air passengers, may justify even substantial negative economic consequences for certain economic operators (para. 48), and the consequences as a result of extraordinary circumstances, such as the eruption of a volcano, cannot be considered disproportionate to the aim of ensuring a high level of protection for passengers (para. 50).

Noticing the imbalance between the interests of passengers and air carriers, numerous scholars have continuously requested to pay some consideration to the protection of the interests of airlines, in particular, in face of the circumstances that cause interruptions to business (Correia, 2014, p. 249). Attempts have already been made to limit the obligation to offer assistance and care to air passengers, both in the recent proposal of 2020 to change the Regulation and in the one discussed in 2013. In particular, the proposals for changing the Regulation focused on the establishment of a flat rate for accommodation and the limitation of accommodation provision to a maximum of three (3) nights.

In this regard, it is also essential to observe that it was consistently claimed that assistance for passengers affected by long delays or cancellation was often not provided as envisaged by the Regulation (European Consumer Centres Network, n.d., p. 4). Therefore, it is not clear to what extent the airlines are suffering financial losses due to the implementation of this obligation during Covid-19. Partially, the insufficiency of adequacy and quality, or even absence, of assistance may be the result of: the unclear provisions of Article 9; the absence of the definitions of *snacks*, *meals,* or *refreshments*; or a broad discretion left to the air carrier in the implementation of this Article (European Court of Auditors, 2018, p. 11). Therefore, the proposed changes to the Regulation, clarifying the scope of the obligation to care and assist, are welcome not only in the context of super-extraordinary circumstances but also for the enhancement of air passengers' protection in general.

Since the above-mentioned proposals are not yet accepted, the right to care remains limited only through the application of the principle of proportionality, which, if argued well, may reduce the burden on air carriers. As

mentioned above, the Court has accepted the possible negative consequences of the economic operators who have the obligation to ensure the protection of air passengers (*Denise McDonagh v. Ryanair Ltd,* 2013, para. 48). However, the situation in the *McDonagh* case, although serious enough to deprive different air carriers of part of the fruits of their labour and of their investments, did not threaten their existence nor the stability of international air transportation as a whole. This might shift the axis of the balance in favour of the protection of the interests of air carriers in the assessment of the extent of care to be provided during the pandemic for those awaiting another flight, as well as the amount of compensation to be paid if a passenger was not assisted. However, since the consumer-oriented approach has been constantly followed in recent years by both the legislator and the CJEU (Correia, 2014, p. 249), a significant shift in practice can only be made by changing the Regulation – tackling the present asymmetry via the differentiation of extraordinary circumstances.

5. Conclusions

The majority of epidemics and pandemics, including Covid-19, satisfy the cumulative conditions for characterising their events as extraordinary circumstances established in the case-law of the CJEU, since these events by nature or origin are not inherent in the normal exercise of the activity of air carriers and they go beyond the actual control of that carrier on account of their nature or origin. However, not all of these events may result in exemption from paying compensation to air passengers if the result of such events is the cancellation of a flight. It is necessary to establish the causal link between the extraordinary circumstances and the delay or the cancellation, and to take all reasonable measures to avoid the delay or cancellation or its negative consequences. The same requirements are applicable to Covid-19, since Regulation 261/2004 does not foresee a special group of extraordinary circumstances.

To strike a better balance between the interests of air passengers and air carriers, it is recommended to rethink the concept of extraordinary circumstances and differentiate the extent of the protection afforded to both groups based on the gravity of the situation. The introduction of vouchers as an equal alternative form of reimbursement upon the choice of the carrier in certain circumstances, combined with all the guarantees afforded to this form of reimbursement, may be worth discussing in seeking to strike a better balance between the sustainability of business and the protection of air passengers as a whole. The restriction of the obligation to provide accommodation, limiting it in time and amount considering the relevant circumstances and the principle of proportionality, might not only help to tackle asymmetry between the protection of vital interests in situations such as Covid-19, but also enhance consumer protection, affording more clarity and thus more awareness and willingness on behalf of air carriers to comply with the obligation.

Abstract. The authors raise the actual problem of weak intersectoral interaction of subjects of the financial-credit and innovation sectors of Kazakhstan. Currently, asymmetric processes are observed not only in the interaction of two strategically important sectors for the economy, but also in the asymmetric nature of the impact of regulatory instruments on the process of their interaction. This is a consequence of a largely non-integrated and disproportionate government policy, which in recent years has been characterized by one-sidedness and narrow focus in stimulating and supporting certain sectors and industries. In this regard, the authors carried out a three-level assessment of dependencies to determine the degree of influence of innovation activity on the rate of economic growth, the degree of influence of financial-credit organizations on the results of innovation activity and the degree of influence of the current regulatory instruments on the investment activity of the financial sector. As a result of the construction and use of an econometric model, results were obtained that confirm the hypothesis formulated by the authors about the creative role of systemic regulation, but also reveal the existing potential and points of convergence of financial-credit organizations with the innovative sector of the economy.

Keywords: financial and credit organizations; innovation sector; intersectoral interaction; regulatory institutions

1. Introduction

In modern conditions of global geopolitical changes, volatility in the commodity and financial markets, frequent cyclical fluctuations and the rapid growth of integration processes, the issues of ensuring sustainable development of the national economy by deepening the diversification of its structure and increasing competitiveness in the field of innovations in the real sector of the economy come to the fore. These issues are especially relevant for Kazakhstan with a slowdown in economic growth and continued dependence of the economy on the income of the oil and gas sector. The existing practice in the country of relations between the financial and innovation sectors of the economy shows that even with the presence of potentially successful ideas, the desire to financially support these projects is reduced to almost zero due to the low risk appetite of financial and credit institutions and the tightening requirements of the financial regulator. The emerging trends, the presence of unsolved problems and at the same time the accumulated potential of private financial and credit organizations in Kazakhstan emphasize the ambiguity and relevance of this study, the need for a critical rethinking of the process of regulation the activities of financial and credit organizations for more effective interaction with innovative enterprises in the new conditions of the development of the world economy.

2. Theoretical background

Currently, the role of state regulation as a direction in resolving these problems is growing. Many scientists and experts are of the opinion that the solution of the complex task of reorienting investments in the sphere of expanded reproduction and modernization of fixed assets in the real sector is impossible without embedding incentives in the process of macro regulation. Moreover, the experience of a number of countries in America, Asia and Europe (period 1997-2010) testifies to the productivity of this regulatory paradigm (Pradhan, Arvin, Nair, Bennett, 2020). Overcoming the increased appetites of monopolies and financial and credit structures, reorienting them to meet the financial needs of the real sector, will possible only with government support and stimulation of structural and technological restructuring of the economy by stimulating innovation (Rakhmetova, 2015)

The analysis of problems about the relation between the financial and innovative sectors of the economy' study indicates that there is a link between indicators of the development of the financial sector, real innovation and economic growth (Majeed, Iftikhar, Atiq, 2019). Some studies are devoted to the interaction of various factors (Niyazbekova, Grekov, Blokhina, 2016). For example, a study of 6,422 enterprises in 22 emerging economies found that lack of an access to credit resources hinders innovation. This statement is particularly true for firms that are limited in alternative sources of financing (Qi, Ongena, 2020). Studies of Spatareanu M., Manole V., Kabiri A. emphasize the importance of bank financing for the innovative activities of British firms. The authors found out the problems of stability of banks during the crisis of 2008 and 2011 affected the innovative development of companies negatively (Spatareanu, Manole, Kabiri, 2019). In the study of Khan MK., Kaleem A., Zulfigar S., Akram U. the relation between the various sources of financing used by Chinese firms and the intensity of their research and development were analyzed. The choice of funding source for research and development depends on financial constraints (Khan, Kaleem, Zulfigar, Akram, 2019).

Wang HZ., Yin DS., Zhang XTTN., Zhen XT. applied regression analysis to investigate universal banks as an important source of external financing and their impact on the results of innovative activity of borrowing firms. The authors also explore other sources of funding for innovation in firms (Wang, Yin, Zhang, Zhen, 2019). A study of the use of bank credit lines to finance research and development investments based on the data of 939 firms from 17 European countries was conducted by a group of researchers Guney Y., Karpuz A., Ozkan N. The results of the study showed that provided credit lines had a positive and significant impact on investment in

research and development (Guney, Karpuz, Ozkan, 2017). Kim S., Lee H., Kim J. investigate the various effects of external financing (bank loans, equity and bond issues) on the technological innovation activities of Korean listed companies. They found that indirect external financing through bank loans affected the technological innovation activities of Korean firms negatively, while direct external financing through the issuance of securities had a positive impact (Kim, Lee, Kim, 2016).

A significant part of the research was conducted on the basis of panel and time series data using standard regression equations, including the introduction of various significant variables (factors that are significant for the result). Researchers Diamond D, Weinrich G., Kaas L. in their work used a model of dependence between the indicator of economic growth and the endogeneity of behavioral strategies of banking system subjects (Kaas, 2018). As a basis, scientists had taken such types of assets as money supply and securities (corporate shares and government bonds). Evidence of growth of the money supply that leads to a decrease in the yield on government securities, and to an increase in the yield on corporate shares had been uncovered. In turn, the direction of bank investments in corporate stocks encourages economic growth.

The endogenous growth model reveals a non linear relationship between the rate of economic growth and the performance of the banking sector by Dieda L., Fatya B. In particular, scientists have identified a contradictory impact of the activities of banking sector entities on the economy: positive – increasing trends in the division of labor and specialization, and negative - competition between banking sector entities and increased speculation in the stock market (Deidda, 2002). Authors Hung F. and Kosren R. we applied a non-linear model of endogenous growth and identified the impact of bank credit operations on economic growth through innovation financing. As in previous models, the ambiguous impact of the credit mechanism on economic growth is shown here (Hung, 2012).

We believe that the fundamental basis for the prevention of emerging contradictions in the context of intersectoral interaction between the financial-credit and innovation sectors of the economy is the adjustment of the vector of the current system of state regulation. In this regard, the central hypothesis of this study is to identify the role of state systemic regulation on the nature and quality of interaction between the financial-credit and innovation sectors, and, as a consequence, on economic growth. Our hypothesis, in context of a systems approach, allows us to formulate the following questions: 1) What is the impact of innovation in the real sector on the rate of economic growth? 2) What is the impact of various sources of investment financing on the growth of innovation? 3) What is the role of the assets of financial-credit organizations in financing real innovations? 4) What is the degree of influence of government regulation instruments on the activities of financial-credit organizations, on the intensity and trajectory of intersectoral interaction? – which we check using correlation-regression analysis.

3. Research objective and methodology

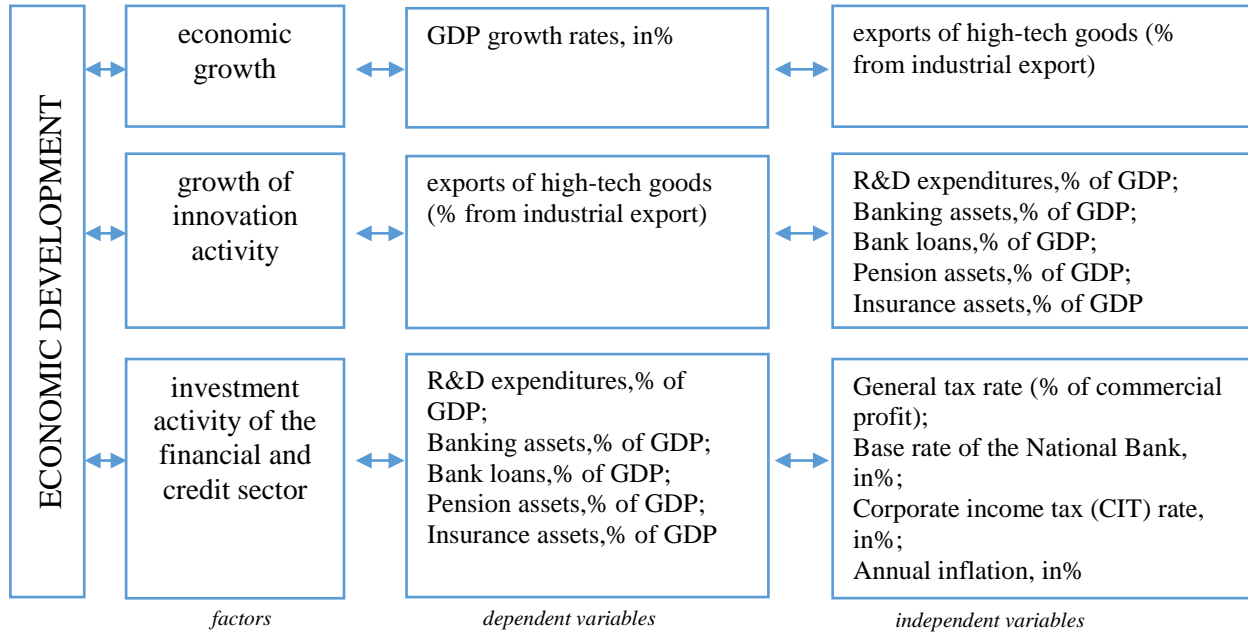
To confirm our hypothesis about the role of regulatory measures on the interaction of financial-credit and innovation sectors, within the framework of this scientific study an economic and mathematical model was developed. The novelty of the research is the application of an integrated approach to the construction of an economic and mathematical model based on the identification of a causal relationship at three levels: the first level – the impact of the results of innovative activities on economic growth; the second level is the influence of financial assets on the growth of the innovation sector and the third level – the influence of regulatory instruments on the investment activity of financial and credit institutions (Figure 1).


Figure 1. Logic and structure of the conducted econometric research

Source: compiled by the authors

For empirical data analysis, we applied econometric modeling methods, in particular corrrellation-regression analysis with the construction of paired and multiple linear regression models. The choice of corrrellation-regression model is due to the fact that it is this model that allows us to confirm our hypothesis and answer the formulated questions as much as possible. The PPP Stata 13 was used as a modeling tool and graphical illustration of dependencies was performed in Excel. The statistics were taken from World Bank's international database (www.worldbank.data.org) and databases of the National Bank of the Republic of Kazakhstan for the last 25 years from 1993 to 2017 (www.nationalbank.kz). It should be noted that the research limitations in the modeling being carried out were certain indicators, the values of which were not available due to their absence in the statistical databases we used (such as reserve rates in the context of financial-credit organizations, the share of medium-term loans issued to enterprises of the innovation sector, the share of pension and insurance assets invested in securities of enterprises of the innovation sector, etc.)

4. Results and discussion

1. To assess the first group of relationships (the impact of innovation results on economic growth), we used an indicator reflecting economic growth – GDP growth rates (gross domestic product) in % per year and an indicator of innovation performance – exports of high-tech goods, as a % of industrial exports. The dependent variable was the GDP growth rate (% per year) for the study period. The indicator of exports of high-tech goods (in % of industrial exports) was used as an independent variable. The correlation analysis showed a weak causal relationship between these variables, since the correlation coefficient between GDP growth rates and exports of high-tech goods was equal *to r* = 0.18 (Figure 2).

Figure 2. Diagram of dependence between GDP growth rates and the results of innovation activity in the Republic of Kazakhstan

Source: compiled by the authors

The regression equation has the following form:

$$GDP = 2,1782 + 0,0925 Inn$$
$$(2,27) \quad (0,11)$$

where:
GDP - GDP growth rate (% per year),
Inn - exports of high-tech goods (% from industrial export).

Obtained results show that exports of high-tech goods in Kazakhstan do not affect the GDP growth rate in this period significantly, which confirms the thesis that economic development in Kazakhstan is still determined by the historically established structure of the economy, the development of which is mainly due to income from raw materials exports and investment growth in traditional sectors of the extractive sector. At the same time, recent trends in the development of the global economy, which are mainly characterized by frequent cyclical fluctuations and geopolitical changes in the world, require deeper diversification and effective structural adjustment in Kazakhstan strongly. However, in countries with more diversified economies and less dependence on mineral exports, on the contrary, there is a correlation in the first group of indicators (table 1). In particular, the countries with the largest innovation component that affects GDP growth rates include the United States (0.089,/0.15), Sweden (0.198/0.11), (United Kingdom (0.173/0.26).

Table 1. Models of dependence of GDP growth rates on exports of high-tech goods in cross-country context

Country	Constant	Regression coefficient	R^2
United States	0.279 (1.153)	0.089* (0.044)	0.15
Sweden	- 0.237 (1.848)	0.198 (0.117)	0.11
United Kingdom	- 2.119 (1.515)	0.173*** (0.059)	0.26

Note: Standard errors are shown in parentheses: * denotes significance at the 10 percent level;
* * denotes visibility at the 5 percent level; * * * denotes significance at the 1 percent level.

Source: compiled by the authors

2.   Within the framework of modeling indicators for the second group of dependencies (the impact of financial assets on the growth of the innovation sector), we have made an attempt to determine the degree of the greatest impact of various sources of innovation financing on the growth of the innovation sector. In this regard, we have grouped all existing relevant factors that can influence the growth of innovation in domestic conditions into appropriate groups, in order to assess the degree of correlation with the performance indicator of the innovation sector for each group (table 2).

Table 2. Grouping of sources of innovation financing indicators

Investment	Bank loans	Assets	Stock market
1 group	2 group	3 group	4 group
R & d expenditures (I_1, % of GDP)	Domestic credit to the private sector by banks (C_1, % of GDP)	Banking assets (A_1, % of GDP)	Market capitalization of listed domestic companies (F_1, % of GDP)
Fixed capital investment (I_2, % compared to the previous year)	Long-term bank loans to legal entities (C_2, % of GDP)	Pension assets (A_{A2}, % of GDP)	Shares outstanding, total value (F_2, % of GDP)
Foreign direct investment (I_3, % compared to the previous year)	Short-term loans of second-tier banks (C_3, % of GDP)	Assets of insurance companies (A_3, % of GDP)	

Source: compiled by the authors

The sources of statistical data for this group of dependencies were statistical indicators from the World Bank database (www.worldbank.data.org), National Bank of the Republic of Kazakhstan (www.nationalbank.kz) and the Committee on statistics of the Ministry of National economy of the Republic of Kazakhstan (economy.gov.kz) for the period from 1995 to 2018. The obtained data was previously systematized and grouped. The choice of the indicator "export of high-tech goods in the total volume of industrial exports" is justified by the fact that the practice of determining key indicators in the development of the innovation sector of Kazakhstan and economically developed foreign countries differs significantly. Thus, the main indicators in the field of innovation development, which are calculated by domestic statistical agencies, are mainly quantitative data (number of patents, the number and share of innovative-active enterprises, the number of enterprises, the share of research and development expenditures implementing high-tech innovations, etc.) in Kazakhstan, but the methodology of World Bank uses as a key indicator in the field of innovation development an indicator, that reflects, in our opinion, the final result of innovative entities – "the share of high-tech products in the total volume of industrial exports», which we took as a dependent variable. For each group of factors, a correlation analysis of the relationship with the indicator of exports of high-tech goods in the Republic of Kazakhstan (*Inn*, % of industrial exports) was conducted and a corresponding regression model was developed.

The regression equation in this case has the following type:

$$Inn = 78{,}88 + 78{,}33 \cdot I_1 - 0{,}22 \cdot I_2 - 0{,}14 \cdot I_3$$
$$\quad (10{,}9) \quad (29{,}6) \qquad (0{,}05) \qquad (0{,}07)'$$

In particular, the results of analysis of the first group of factors ("investment») also have shown that there is a feedback link between exports of high-tech goods in Kazakhstan and expenditures on research and development (R & d) ($r_{Inn,I_1} = -0{,}52$). The obtained result confirms the thesis that the quantitative growth of innovation

activity indicators, including the growth of research and development expenditures, do not provide a guaranteed impact on the quality of work of subjects of the innovation sector in the Republic of Kazakhstan and, above all, on the results of their activities. In this case, we should note the weakness of the institutional infrastructure represented in Kazakhstan by a network of specially created development institutions (JSC "National Agency for technological development" (LLC «Natr»), JSC "Development Bank of Kazakhstan", JCS "QazTech Ventures", Kazakh Export, Kazakhstan project preparation Fund, etc.) which are aimed at stimulating the growth of the national economy at the expense of public funds. However, the activities of these organizations on the background of realization of strategy of industrial-innovative development, in our view, without full competition from private financial-credit institutions, as it can be seen from the obtained results, work only for the execution of mainly quantitative indicators (The concept of development of financial sector of Kazakhstan until 2030, State program of industrial and innovative development of the Republic of Kazakhstan for the period 2015 -2019). Moreover, both investments in fixed assets and direct foreign investments do not show a positive effect on the resulting indicator ($r_{Inn,I_2} = -0.53$; $r_{Inn,I_2} = -0.48$) (Figure 3).
Figure 3

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810

**Figure 3.** Diagram of the dependence of innovation performance on a number of indicators: research and development expenditures, foreign investment and investment in fixed assets in the Republic of Kazakhstan

Source: compiled by the authors

This result is not accidental, it confirms the choice of Kazakhstan's industrial sector enterprises, of the so-called, "catch-up development" model according to which the owners of enterprises (both domestic and foreign investors) do not invest resources in innovative development, but purchase ready – made high-tech equipment in partner countries in order to level the time factor. The use of ready-made foreign equipment and technologies is evidenced by the activities of such industrial companies as: JSC "Arcelor Mittal Temirtau", LLP "Corporation Kazakhmys», «Tengizchevroil","Karachaganak Petroleum", and others that work in the extractive sector [18].

Assessment of the impact of factors of the second group ("Bank loans») showed the strongest correlation with the export of high-tech goods indicators of domestic lending to the private sector and long-term bank lending to legal entities, since the pair correlation coefficients have values $r_{Inn,C_1} = 0.62$; $r_{Inn,C_2} = 0.65$. At the same time, short-term loans from second-tier banks do not have a positive impact on the development of innovations, since поскольку $r_{Inn,C_3} = -0.06$. This can be explained by the fact that the terms of short-term lending and the conditions for its provision do not coincide with the duration of the full innovation cycle.

Taking into account the fact that the indicators of domestic lending to the private sector and long-term lending to legal entities are very closely interrelated, it is advisable to evaluate separate models:

$$Inn = 5.43 + 0.49 \cdot C_1$$
$$\quad (4.61) \ (0.14)$$

and

$$Inn = 16.0 + 1.8 \cdot C_2 - 3.03 \cdot C_3$$
$$\quad (3.86) \ (0.25) \quad (0.65)$$

All regression coefficients are statistically significant. At the same time, with an increase in the share of domestic loans to the private sector in GDP by 1%, the share of exports of high-tech goods in industrial exports will grow by 0.49%. Similarly, an increase in the share of long-term bank loans to legal entities in GDP by 1% will contribute to an increase in the share of exports by 1.8%. While an increase in the share of short-term bank loans in GDP by 1% leads to a decrease in the share of exports by 3.03% (Figure 4).
Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810
Figure 4. Diagram of the dependence of the results of innovation activity and indicators of bank lending, including the context of credit terms in the Republic of Kazakhstan

Source: compiled by the authors

The evaluation of the influence factors of the third group ("assets") for the performance indicator of innovative activity (high-technology exports in total industrial exports) in the Republic of Kazakhstan to the greatest extent on the resulting sign is influenced by the assets of insurance companies ($r_{InnA_3} = 0.79$) and to least extent – pension assets ($r_{InnA_2} = 0.56$). Total bank assets have a weak impact on the result ($r_{Inn\& a_1} = 0.11$). The regression model has the following type:

$$Inn = 20.85 + 0.33 \times A_1 + 1.89 \times A_2 + 29.4 \times A_3$$
$$(8.89) \quad (0.12) \qquad (0.97) \qquad (6.02)$$

Thus, with an increase in the share of banking assets in GDP by 1%, we can expect an increase in the share of exports of high-tech goods in industrial exports by 0.33%. In turn, if the share of pension assets increases by 1%, the share of exports of high-tech goods will increase by 1.89%. An increase in the share of assets of insurance companies will contribute to the growth of exports of high-tech goods by 29.4% of industrial exports (Figure 5).

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810

Figure 4. Diagram of the dependence of the results of innovation activities and various types of financial assets in the Republic of Kazakhstan

Source: compiled by the authors

Thus, despite the still insufficient role of insurance sector entities in the development of the domestic economy (no more than 1 trillion tenge or 1.8% of GDP), insurance sector entities, due to the concentration of long-term resources, have a great potential to interact with the subjects of the innovation sector (Kalkabayeva, Kurmanalina, Gusmanova, 2017). The term of placement of long-term insurance resources coincides with the duration of the innovation process (on average 7-10 years). This confirms the prospects of using insurance savings in the interests of economic development, as it happens in economically developed countries. Thus, the share of insurance resources in the structure of venture business financing in the European Union has reached 15% (www.ec.europa.eu/eurostat). At the same time, pension assets play an even greater role in the development of innovations here, their share in the structure of venture business financing has reached 25%, exceeding the share of investment by the banking sector in the development of innovations. Of course, the similar nature of the formation of insurance and pension resources, as well as successful international practice, indicate the prospects for their use. The inconsistency of the result obtained for pension assets indicates the imperfection of regulatory institutions of financial organizations in terms of their interaction with subjects of the innovation sector, and the current practice of strict regulation, as well as in relation to subjects of the banking sector, which reduces their role in the development of the domestic innovation sector (Rakhmetova, Kalkabayeva, Iskakova, Kurmanalina, Turmakhanbetova, 2019).

Studing the degree of influence of factors of the fourth group ("stock market»), which characterize trends in the development of the stock market in Kazakhstan, it is necessary to highlight the indicators "market capitalization of listed domestic companies" and " value of shares in circulation». However, the obtained results showed that these indicators do not affect the indicator "export of high-tech goods» significantly. The coefficients of paired correlation coefficients between these indicators are $r_{InnF_1} = 0.005$ and $r_{InnF_2} = -0.19$ respectively. The same result is given by a regression analysis of the dependence of innovations on the stock market indicators:

$$Inn = 24,5 + 0,13 \cdot F_1 - 1,44 \cdot F_2$$
$$(4,78) \quad (0,25) \quad \quad (1,59)$$

3.   To assess the third group of relationships (the impact of regulatory instruments on the investment activity of financial and credit sector entities), we set the task of assessing the degree of influence of regulatory instruments on key indicators of the main sectors of the financial market. In particular, the results of regression analysis presented in table 3 show that the regression equation in terms of the impact of regulatory instruments on the dynamics of bank lending is statistically significant. The 75% variation in loans to the private sector is explained by changes in the factors included in the model. All coefficients of the equation, except the coefficient before the "total tax rate" indicator, are statistically significant.

Interpretation of regression coefficients, all other things being equal, gives the following results: - with an increase in the refinancing rate by 1%, we can expect a decrease in bank loans to the private sector in GDP by 0.41%; - with an increase in the CIT rate by 1%, the share of bank loans to the private sector in GDP will decrease by 2.4%; - if the inflation rate rises by 1%, the share of bank loans to the private sector in GDP will increase by 0.85%.

Table 3. Model of dependence between bank loans to the private sector and regulatory instruments in the Republic of Kazakhstan

Dependent variable: Domestic credit to the private sector by banks (% of GDP)

- in general, the regression equation is statistically significant. The 95% variation in the resulting indicator, namely, insurance sector assets, is explained by the regressors included in the model;

- insignificant coefficients are the coefficients of the equation for the variables "share of securities" and "specific weight of bank deposits in the investment portfolio of the insurance sector». The remaining coefficients are statistically significant with a probability of 95%;

- with an increase in the insurance sector's asset diversification ratios invested in non-government securities and in deposits of one Bank by 1%, the insurance sector's assets in GDP will increase by 3.96 and 2.57 %, respectively;

- if the total tax rate increases by 1%, the assets of the insurance sector will decrease by 0.06%. At the same time, gross inflation, on the contrary, will contribute to an increase in assets of the insurance sector by 0.05%.

Table 5. Model of pension sector assets dependencies and regulatory instruments in the Republic of Kazakhstan

Modeling the dependence of pension sector assets on regulatory instruments (table 5) led to the following conclusions:

- the 91% change in pension sector assets is explained by changes in regulatory instruments. The regression equation is statistically significant;

- insignificant for our data were "the share of non-state securities issued by issuers" and "the share of second-tier banks deposits in the pension sector's investment portfolio», as well as the "annual inflation rate ".

- statistically significant instruments based on the sample data under study are: the "investment limits of pension assets in non-government securities of organizations and in deposits and financial instruments of second-tier banks" and "total tax rate";

- if the investment limits of pension assets in non-government securities, as well as in second-tier banks deposits and financial instruments increase by 1%, the share of pension sector assets will decrease by 33.7 and 29.2, respectively;

- with an increase in the tax rate by 1%, pension assets are expected to decrease by 0.14% .

5. Discussion

The obtained results by applying an economic and mathematical model allowed us to formulate the main conclusions in the context of this scientific study:

The absence of dependence between the results of innovation activity in Kazakhstan and the dynamics of GDP growth was revealed against the background of such dependence in economically developed countries, which occupy leading positions in the global innovation index, which confirmed the thesis about using "catch - up development" model, and the main factor of economic development is still the income of the extractive sector.
There is an inverse relationship between research and development expenditures and innovation results, which indicates the ineffectiveness of specially created quasi-public sector development institutions that work primarily on the implementationof quantitative indicators.

It was confirmed that investments in fixed assets and foreign investment also do not significantly affect the results of innovation activities, which indicates the direction of investment flows mainly in branch, technology and equipment of the extractive sector.

Significant potential impact of bank loans on the results of innovation activity has been confirmed, first of all, long-term bank loans, the timing of which corresponds to the duration of the competitive innovation cycle, which determines the prospects for their use in contrast to short-term loans, for which such a dependence is not observed.

There is a strong correlation between the assets of insurance companies and the results of innovation activity, which indicates the existing potential of the insurance sector, including pension assets; the effective use of long-term assets of the insurance sector in favor of subjects of the innovation sector is successfully confirmed by world practice.

As expected, the instruments of the securities market did not show an impact on the results of innovation activity due to the least developed structure of the financial market and the lack of practice of using securities by real entities (including the innovation sector).

It is shown that there is no strong dependence of the activity of financial market entities on the inflation indicator, which should become the basis for eliminating distortions in the implementation of the monetary policy of the regulator, which aggravates and preserves problematic nodes in the interaction of the financial and credit and innovation sectors of the economy.

The results confirming the influence of state regulatory instruments on the activity of banking sector entities, in which refinancing rate and corporate interest rate had the greatest correlation, are presented. It is the state, as the regulatory bodies is actively involved in the implementation of integrated economic policy, that, as world practice shows, is subject to adjust and stimulate the activities of commercial banks so that they are more actively involved in the innovation sector.

The results confirming the influence of instruments of state regulation of activity of subjects of insurance sector, the structure of which has the greatest correlation show the set standards for diversification of assets of the insurance sector and tax burden, which speaks about the potential impact of regulatory options on business entities of the insurance sector (including pension fund) with the aim of enhancing their interaction with actors of the innovation sector. The injection of resources of insurance and pension funds, which has a long-term investment character corresponding to the duration of the full innovation process, is blocked by the rather strict regulatory practice of the financial regulator. We believe that the current practice of placing these funds in highly liquid securities of foreign banks and companies should be focused on investing resources primarily in domestic economy (the experience of Norway and other European countries) taking into account the establishment of an appropriate anti-corruption mechanism and the development of a mechanism for repayment and efficient utilization of these resources in the manufacturing and innovation sectors of Kazakhstan.

The authors point out the asymmetry in the work of the public system of regulation of intersectoral interaction, which is confirmed by the weak institutional infrastructure, centralized innovation policy in the country's industries and regions against the background of the long-term implementation of the state program of industrial and innovative development.

6. Conclusion

Thus, the pronounced processes of globalization and trends in financial and economic turbulence today have exacerbated issues related to ensuring the sustainable development of national economic systems, including on the basis of harmonious intersectoral interaction of various economic entities. This study attempts to model country panel data in order to prove the significant impact of the regulatory system on the intensity and quality of interaction between two strategic sectors for any economy – financial-credit and real (including innovative) sectors of the economy against the background of a strong correlation between the rates of economic growth and the innovation component.

Among other things the ability of the process of interaction between financial and real (including innovative) sectors of the economy simultaneously generate the effects (expected results at different levels) as a result of system element determines the conduct of cross-national comparative analysis of the role of interaction of economic sectors to determine their current and future positioning. The results of the analysis showed that Kazakhstan's lag behind a number of developed countries was caused by various institutional conditions affecting the potential and capabilities of interacting sectors.

INVESTMENT INCENTIVES AS INSTRUMENT OF MOTIVATION OF FIRMS AND ECONOMIC STABILIZATION[*]

Petr Musil [1], Veronika Hedija [2]

[1,2] Department of Economic Studies, College of Polytechnics Jihlava, Tolstého 16, 586 01 Jihlava, Czech Republic

E-mails:[1] Petr.Musil@vspj.cz ; [2] Veronika.Hedija@vspj.cz

Abstract. Investment incentives are mostly presented as an efficient tool of economic policy to eliminate negative impacts of economic cycle and also as the tools of motivation of firms to generation of investment. The aim of the paper is to verify the relationship between investment incentives and business cycle in the Czech Republic. There is used the data of CzechInvest, Czech Statistical Office and Organisation for Economic Cooperation and Development. To verify the link between the investment incentives and the business cycle, the Pearson correlation coefficient and Spearman correlation coefficient was used. There has been identified moderate positive relationship between the volume of the state support and the growth of the gross domestic product in constant prices. The link between investment incentives and output gap was not statistically significant. The study brings new insights on the field of investment incentives as an instrument of stabilization of economy. Investment incentives are important in terms of stimulating the investment activity of firms. Findings of the study answer the question of whether the government behaves responsibly in the area of investment incentives. The findings show that the policy of investment incentives does not respond flexibly to the current needs of the Czech economy.

Keywords: investment incentives; business cycle; Czech Republic; economic stability; gross domestic product

JEL Classifications: E22, E32

1. Introduction

An investment incentive can be understood as a measurable advantage granted by a government to a particular firm, firm or group of firms in order to induce them to behave. By using investment incentives, the state seeks to encourage an increase in the volume of investments in its territory (Srholec 2004). The investment incentive can be provided by the state in practically two ways. Direct financial support or indirect relief from state requirements to companies or individuals. Direct support may be represented by a subsidy for the purchase of machinery, land, infrastructure, equipment or other means of production. On the other hand, reliefs take the form of a reduction or total remission of taxes, duties, social security contributions, as well as exemptions from the obligations imposed on entities by the legal order.

The objectives of investment incentives may vary. Sometimes they are advocated to support less developed regions affected by the structural crisis, high unemployment and low living standards. At other times, economic policy makers expect investment incentives to contribute to the establishment of macroeconomic equilibrium, particularly with regard to the business cycle. If economic activity in the country is declining, unemployment tends to grow, then there should be an incentive that motivates the investor to allocate his capital to the economy that offers the incentive. Investment incentives began to be used more extensively in the Czech Republic in 1998, when the domestic economy underwent its first major recession after most of the measures for economic transformation were implemented (Žídek 2006). This was a direct consequence of the 1997 currency crisis, which spilled over into the real economy in the coming months.

Promoting investment as an effective remedy for economic downturn is entirely in line with the economic theory based on the teachings of John Maynard Keynes and his followers. Keynesians rely on the interconnection of the multiplier and accelerator principles to drive aggregate demand and thus help restore economic performance to its potential (Dornbusch, Fischer 2013). On the basis of this logic, massive support for investment by the state should come just at a time of decline in gross domestic product, and on the contrary, in times of rapid economic growth, the state should save on investment incentives. Accordingly, the volume of supported investments should also evolve, which should be countercyclical.

The aim of the paper is therefore to assess whether investment incentives have been treated in this way in the past 20 years. In particular, to assess the relationship between investment incentives in the Czech Republic and the evolution of the output of the economy and to assess whether the investment incentives were used to act counter-cyclically.

The findings of the study help us to answer the question of whether the government behaves responsibly in the area of investment incentives and whether their setting does not contribute to the deepening cyclical fluctuations of the economy.

2. Literature review and theory development

Investment incentives can be seen as one of the possible instruments for promoting economic growth, but also as an instrument for stabilizing the economy.

According to traditional macroeconomic theory, investment is one of the factors determining the level of equilibrium output of the economy and is also an important factor of economic growth. The increase of

investment in the country leads to an increase in aggregate demand and thus also to an increase in the real output of the economy. The accumulation of investment contributes to the growth of the country's production potential and thus to the growth of potential output (Dornbusch, Fischer 2013).

The impact of investment on the performance of the economy is examined by a number of empirical studies. These confirm the positive impact of investment on economic growth in most cases (Khan, Reinhart 1990; Anderson 1990; Bal et al. 2016). The empirical studies also confirm that the private investment appears to have a higher pro-growth effect compared to government investment (Khan, Reinhart 1990). Investment incentives can be seen as one of the possible instruments for promoting economic growth, but also as an instrument for stabilizing the economy.

According to traditional macroeconomic theory, investment is one of the factors determining the level of equilibrium output of the economy and is also a factor of economic growth. The increase in investment in the country leads to an increase in aggregate demand and thus also to an increase in the real output of the economy. The increase in investment as such contributes to the growth of the country's production potential and thus to the growth of potential output (Dornbusch, Fischer 2013).

The impact of investment on the performance of the economy is examined by a number of domestic and foreign studies. These mostly confirm the positive impact of investment on economic growth (Khan, Reinhart 1990; Anderson 1990; Bal et al. 2016). Private investment also appears to have a higher pro-growth effect compared to government investment (Khan, Reinhart 1990). The positive effect of investment on economic growth can also be found also in the Czech Republic. Křístková (2012) examines the impact of investment in science and research on economic growth in the Czech Republic. It concludes that these investments contribute to economic growth, but their impact is lower than that of investments in capital goods.

Some studies focus on examining the relationship between investment and the business cycle. According to Levy Yeyati et al. (2007), the economic cycle can affect investment through multiple factors. In the period of expansion (when the output is above the level of potential product) companies have higher incomes and profits and these motivate them to invest both in the home country and abroad. This effect who is referred as the 'income effect' by the authors, will lead to the so-called pro-cyclical behaviour of domestic investment and foreign direct investment abroad. On the other hand, so-called "substitution effect" will result in a situation where the economy is in the phase of expansion. It means that the firms will prefer domestic investment over foreign direct investment abroad. The reason is the expected higher return on domestic investment, as the expected value of investment during the period of expansion is growing. And also lower risk of domestic investment compared with foreign investment, especially those in developing countries. (Levy Yeyati et al. 2007)

The vast majority of empirical studies confirm of the fact that not only domestic investment but also foreign direct investment directed abroad are in line with the economic cycle. They tend to grow as economies are in a phase of expansion and decline in times of recession (for example, Levy Yeyati et al. 2007; Rodriguez, Bustillo 2015).

There are also number of studies examining the impact of investment incentives on economic development and selected macroeconomic indicators. The results of these studies are not uniform. Some studies confirm the positive impact of investment incentives on development of economy (mainly on productivity and employment) (for example Harris, Trainor 2005; Schalk, Untiedt 2000). Other papers do not identify statistically significant effect and these dominated (for example Daly et al. 1993; Bernini, Pellegrini 2011; Yanikkaya, Karaboga 2017).

However, the system of investment incentives varies among individual countries and also the effect of investment incentives policy on development of the county may be country specific. The results for the Czech Republic are not uniform too. Some studies identified the positive effect of investment incentives. For example, Adamek and Rybkova (2015) examined the effect of investment incentives on development of regional unemployment in the Czech Republic. They concluded that investment incentives can promoting employment and development of regions and have positive and statistically significant influence on regional employment. Pícl (2013) examined the system of investment incentives in the Czech Republic and assess their real impacts on the Czech economy. Based on the findings of own survey, he concludes that most of the supported investments would be realized without state financial support and the investment incentives have not significant impact on the level of investment. Bolcha and Zemplinerová (2012) examined the effect of investment incentives on firm real investments and concluded that the effectiveness of investment incentives is very low. The extra investment generated due to invement incentives was at most 26% of contracted amounts.

Some papers mention the negative circumstances of investment incentives, such as distorting the market, changing employment patterns, raising wage levels in poor regions, and thus dragging labour from local employers, we find quite a lot. One analysis is the study by Schwarz et al. (2007) prepared for the Ministry of Industry and Trade of the Czech Republic. The authors conclude that investment incentives merely substitute an insufficient level of key decision-making factors for investors: political stability, law enforcement, low taxes, functioning infrastructure and the quality of the workforce. Investment incentives are thus only at best the second best alternative if the government is unable to ensure the required level of these factors.

Although the real effect of investment incentives on economic output and economic growth is not clear, it is an important and frequently used instrument of economic policy.

3. Data and methods

The article aims to evaluate the relationship between the amount of investment incentives and the development of economic output. The data needed to assess the relationship are drawn from three sources. The first is CzechInvest, then the Czech Statistical Office (CSU) and the Organization for Economic Cooperation and Development (OECD).

The data on the amount of supported investments and the level of support (percentage of support of the realized investment) are taken from data provided by CzechInvest (2018). It is a contributory organization subordinated to the Ministry of Industry and Trade of the Czech Republic, whose main objective is to support entrepreneurship and investment and which also provides information on the amount of the granted investment incentives.

The data on the amount of supported investments and the aid intensity in the period 1998-2017 were used. The nominal values of the indicators and the values expressed in constant prices (2015 prices) are used for the calculations in order to adjust for the effect of changes in the price level. Consumer price index, which is derived from data provided by the Czech Statistical Office (2018), is used for conversion to constant prices. The output of the economy and its development is evaluated using the growth rate of real gross domestic product and the estimate of the output gap in 1998-2017. These data are drawn from data provided by the Czech Statistical Office (2018a) and data provided by the OECD (2018).

Pearson's correlation coefficient is used to assess the relationship between the amount of investment incentives and the output of the economy, respectively output gap. It is complemented by the Spearman's rank correlation

coefficient (de Vaus 2002). Spearman's rank correlation coefficient makes it possible to identify the relationship even in the case of existing non-linearity. The limits recommended by de Vaus (2002) for the evaluation of dependence in the social sciences are used to assess the strength of the relationship between the quantities under study. The calculations were carried out in the STATA program.

The Pearson´s correlation coefficient is calculated using the following formula:

$$r = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2 \sum_{i=1}^{n}(y_i - \bar{y})^2}} \; . \tag{1}$$

Where x_i and y_i are the quantities between which we investigate the relationship, $\bar{x}$ and $\bar{y}$ are the mean values of x_i and y_i.

The Spearman´ correlation coefficient is calculated as follows:

$$r = 1 - \frac{6\sum(Rx_i - Ry_i)^2}{n(n^2 - 1)} \; . \tag{2}$$

Where Rx_i and Ry_i - represent the order of values x_i and $y_{i.}$.

4. Results

All investment activity was very difficult immediately after the fall of the communist regime in November 1989. Forty years of a centrally planned economy took its toll. Capital was regarded in official circles as a term that was in stark contrast to the ideology of socialism. Accordingly, capital was also treated at the level of state or national enterprises. The result was its total shortage in the early 1990s (Žídek 2006).

It was possible to use foreign capital, but its flow was strictly limited until the mid-1990s. Foreign investment came to the Czech Republic to a very small extent. According to the Czech National Bank (2018), only 19 billion Czech crowns in foreign direct investment came to us in 1993. In 1996 it was almost 68 billion and a breakthrough occurred in 1998, when the Czech Republic for the first time flowed in direct foreign investment over 100 billion Czech crowns.

In the same year, the Investment Incentives Act came into force, on the basis of which domestic and foreign investors could apply for state aid. CzechInvest, which was established at the end of 1992 and is established by the Ministry of Industry and Trade, was in charge of the administration and assessment of applications. While in 1993 CzechInvest managed to make two investments worth 361 million Czech crowns, five years later (and probably due to the launch of investment incentives) it was already 41 investments worth 40 billion Czech crowns. Companies such as Johnson Controls (USA), Panasonic AVC (Japan) or Hella-Behr (Germany) came to the Czech Republic. In the coming years, the inflow of investment into the Czech Republic naturally intensified as the domestic economy became more and more stable and the risk of a reversal of the post-November development

decreased. The accession to the European Union in May 2004 became a definite signal that the Czech Republic is suitable for foreign investments.

Between 1998 and 2017, according to CzechInvest (2018), 1127 investment projects benefited from some form of state support, of which 53 percent were from abroad. Over 15 percent are in Germany, less than 5 percent in Japan or the Netherlands, while other countries occupy lower percentages. The total volume of investments supported by CzechInvest reached 864.3 billion Czech crowns in the period under review. The state supported them with the amount of almost 290 billion Czech crowns. Thus, the average aid intensity was 33.3 percent. In other words, one Czech crown was added by the state to every two Czech crowns invested.

Interestingly, the aid intensity has been decreasing in the long term. It reached its maximum (50 percent) only in 1999 and has been steadily declining ever since. It was the lowest (not counting the first year of existence of investment incentives) in 2016, at twenty percent.
Figure 1. Aid intensity of investments supported by CzechInvest 1998 - 2017 (in %)
Source: CzechInvest (2018), own calculations

As already mentioned, it can be seen from Figure 1 that the aid intensity of investments declines over time. One explanation may be the fact that in the beginning of the examined period the (mainly) foreign investment was still under relatively high political risk in the Czech Republic. And the investors perceived this very sensitively. Therefore, the state compensated them precisely through relatively generous support.

This is also reflected in the rapidly increasing volume of supported investments in 2000 and 2001. The situation is illustrated in Figure 2, where we can see the development of the volume of supported investments in the period 1998-2017. In 2000, supported investments increased by 168 percent year on year, and grew by almost 27 percent in 2001.

Figure 2. Volume of supported investments by CzechInvest in 1998 - 2017 (in millions of CZK)
Source: CzechInvest (2018)

As already mentioned, investment incentives are seen as a highly effective tool for eliminating the negative impacts of the business cycle. Thus, the volume of supported investments could be expected to grow as the economy goes through recession and, on the contrary, will dampen if economic growth shows a solid pace. The volume of supported investments should therefore develop counter-cyclically.
Figure 3. Volume of supported investments by CzechInvest and output gap in 1998 - 2017
(in millions of CZK, output gap in % - right axis)
Source: CzechInvest (2018), Czech Statistical Office (2018)

Figure 3 illustrates the evolution of the volume of supported investment and the growth rate of real gross domestic product over the period 1998-2017. The data show that in the period of growth in the performance of the Czech economy, the volume of supported investments increased and in the period of decline the volume of investment incentives decreased. This shows rather the pro-cyclical use of investment incentives. However, this hard one needs to be further examined for several reasons.

The growth rate of real gross domestic product does not faithfully reflect the business cycle. If the growth rate of real gross domestic product increase, this does not necessarily mean that the economy is reaching potential output. This may reflect the growth of the potential product as such. In other words, real gross domestic product growth is not adjusted for changes in potential output as such. The phase of the business cycle is best illustrated by the output gap, which is estimated as the difference between actual and potential product and is reported as a percentage of potential product.

Further distortion may result from the use of the absolute amount of supported investments. As the price level increases, so does the cost of the investments made and the absolute amounts that investors ask for. The real volume of investments does not need to change. It is therefore appropriate to take this into account in the analysis and to adjust the investment for the effect of the price level change. In assessing the counter-cyclicality of the investment incentives policy implemented, it is also necessary to distinguish between the total volume of supported investments and the actual amount of support, where the percentage of government funds in the supported investment may change over time and as shown in Figure 1 over the examined period.
The Pearson's correlation coefficient (equation 1) is used to assess the relationship between investment incentives and economic performance and the Spearman's order correlation coefficient (equation2) to capture the possible non-linearity of the relationship.

To take into account all of the above mentioned factors, we use alternative indicators for the amount of investment incentives and the output of the economy in our analysis. Investment incentives are used in the form of the total amount of supported investments in millions of CZK (investment incentives) and also as the amount of support that captures the actual volume of government funds directed at investment incentives in CZK million (supported volume). These indicators are examined in nominal and also absolute terms (in 2015 prices) to adjust it for the effect of price level changes. The output of the economy is measured by real gross domestic product growth rate and by output gap.

The results are shown in Table 1 and Table 2. Table 1 deals with the nominal value of investment incentives and the amount of aid, in Table 2 these indicators are adjusted for the price level and enter into the calculation, as already mentioned, in 2015 prices.

Table 1. Pearson´s and Spearman´s correlation coefficients (investment incentives in current prices)

Pearson´s correlation coefficient		
	Growth rate of real GDP (in %)	Output gap (in %)
Investment incentives	0.4284*	0.3372
Support volume	0.4769**	0.2775
N	20	20
Spearman´s correlation coefficient		
	Growth rate of real GDP (in %)	Output gap (in %)
Investment incentives	0.4400*	0.2303
Support volume	0.4325*	0.1310
N	20	20

Note: *** statistically significant at the 1% significance level, ** statistically significant at the 5% significance level, * statistically significant at the 10% significance level.

A statistically significant relationship between the level of investment incentives and the growth rate of real gross domestic product was identified in the examined period 1997-2017. In the years with a higher real gross domestic product growth rate, the amount of investment incentives also increased in the country. Depending on the level of Pearson and Spearman correlation coefficients, the strength of the identified relationship can be described as medium. When comparing the results in Tables 1 and 2, it can be stated that the identified relationship is stronger in the case of investments adjusted for the effect of price level changes (Table 2).

The conclusions are also similar for the relationship between the supported volume and the growth rate of real gross domestic product. Conversely, the relationship between the level of investment incentives and the output gap did not prove to be significant. Moreover, the value of correlation coefficients indicates the existence of a weak or insignificant relationship. Investment incentive policy is thus not used counter-cyclically.

5. Discussion

The findings of this study are not very surprising and show that the investment incentive policy does not respond flexibly to the current needs of the economy in terms of trying to stimulate the economy in times of recession and lower performance and, conversely, to subdue the economy at risk of overheating. Rather, the system appears to be pro-cyclical, with higher real output growth rates and positive corporate expectations motivating firms to invest more, and, if the system permits, they also benefit from investment incentives. As real gross domestic product increases, the amount of total investment incentives and the amount of support also increase.

Bolcha and Zemplinerová (2012) and Pícl (2013) pointed to the low effectiveness of investment incentives in relation to the volume of extra investment genderated due to investment incentives in the Czech Republic. Our findings show that the system si also rather pro-cyclical. From this point of view, the Czech investment incenstives system does not appear effective. Bolcha and Zemplinerová (2012) expect that the abolition of the investment incentives would have only the low effect on the total volume of investment, and it would bring savings in the form of state budget expenditures decline.

The issues of investment incentives impact on the state budget and gross domestic product growth are very interesting and important and deserve the deeper analysis in the Czech Republic. Harms and Meon (2018) show

that the different types of foreign direct investments can have a different effect on economic growth and conclude that greenfield invesments have a stronger impact on growth than mergers and acquisitions. The detailed analysis of the impacts of investment incentives on economic growth in the Czech Republic with a focus on various types of realized investments will be the subject of the further research.

Conclusions

Investment incentives are important in terms of stimulating the investment activity of firms. The article was devoted to the issue of investment incentives and to assessing whether investment incentives were used in the Czech Republic in the period 1998–2017 so that they could contribute to smoothing the economic cycle.

The principles of the system of investment incentives are briefly summarized in the paper. At the same time, it was stated what amount of investments the Czech state has supported through its CzechInvest agency over the past twenty years. Although the system was set up in such a way that entities regardless of their country of origin could benefit from it, initially it was mainly used by foreign investors. Only in recent years did Czech companies "level the score". The ratio of the number of Czech and foreign investors who received the incentive is virtually one to one in two decades.

The aid intensity has been decreasing since the start of the investment incentive scheme. It reached the highest, i.e. 50 percent, in 1999, in recent years it has been between 20 and 25 percent of the total volume of supported investments. Investment incentives can also be used as a tool for economic stabilization. In order the investment incentives could act counter-cyclically, it would have to be true that they are increasing at a time when the economy is below potential output and, on the contrary, declining when the output of the economy is above potential output.

Using the Pearson correlation coefficient and the Spearman order correlation coefficient, the relationship between investment incentives (represented by the total volume of supported investments by actual aid amount) and the performance of the economy (represented by real GDP growth rate and output gap) was tested. A statistically significant directly proportional moderate relationship between the level of investment incentives and real gross domestic product growth rate was identified. In other words, investment incentives, both in terms of total volume and actual aid intensity, grew at the same time as the growth rate of gross domestic product increased. Conversely, in a situation where the rate of gross domestic product growth declined (or was negative), investment incentives declined too. They could thus to some extent act pro-cyclically. On the other hand, the relationship between the level of investment incentives and the output gap, which more accurately reflects the evolution of the economic cycle than the actual growth rate of the real product, proved to be statistically insignificant.

So we can say that the government did not show any tendency to increase investment incentives at a time when the economy was below the potential output and vice versa. The main driver of investment incentives seems to be the interest of companies and investors, which logically grows at a time when the economy is reaching higher growth rates of its performance.

TAX AVOIDANCE: THE ASPECT OF VALUE ADDED TAX[*]

Egidijus Bikas [1], Greta Bagdonaitė [2]

[1,2] *Vilnius University, Suletekio av.9, Vilnius, LT-10222, Republic of Lithuania*

E-mails:[1] egidijus.bikas@evaf.vu.lt ; [2]gretabagdonaite51@gmail.com

Abstract. Tax avoidance is probably as old phenomenon as the taxes themselves. The literature has disclosed that tax avoidance is a worrying problem facing not only the Baltic economies but also the global economy. Tax avoidance and VAT in particular, undoubtedly causes significant damage to the functioning of the public sector and to the financing of public expenditure, because the fiscal significance of this tax is very high. On the other hand, the VAT gap is a significant problem, as in Lithuania in the period of 2012 - 2018 it ranged from 200 to 300 million Euros; the Lithuania's budget lost so much money every quarter. The article aims to identify the factors influencing the VAT gap in the Baltic States. The study is performed using quantitative methods. The influence of optional factors on the VAT gap is determined by performing a correlation-regression analysis of the Baltic States. The study showed that the tax gap, migration and tax rate factors had the largest impact on the VAT gap in the Baltic States.

Keywords: taxation, tax behavioral, tax avoidance, Value added tax

1. Introduction

Taxes are the most important source of state's revenue. The goal of each country is to create a tax system that would promote the growth of the country's economy and ensure sufficient income to perform state functions. Tax revenue is an important factor influencing the efficient performance of state functions, on which not only the state's welfare but also the prosperity of its citizens depends. It is the behavior of taxpayers that determines what

part of tax revenue will be collected to the budget and how efficiently the state will be able to perform its functions.

The main problem facing national governments is decision what and how to tax, what tax rates to apply in order to make the country's tax system fair, simple, efficient and elastic. An unsuitable tax system in a country encourages tax avoidance, which has enormous consequences for the state, because it hinders development of the country's economy and the future of the state.

OECD (2015), Keen (2012), indicate the importance of tax collection in developing countries. The loss of tax revenue estimated at more than $ 3.1 trillion, or about 5.1 % of world's GDP. It means that about 54.9 % of health care expenditure is lost due to the tax avoidance. The impact of tax avoidance is greater in developing countries than in developed countries. Tax justice network (2011) paid attention to the fact that because of tax avoidance 97.7 % of health care budget is lost in African countries and more than one hundred percent in South American countries.

The state provides security and public goods to the entities, and they in return, must pay taxes. However, there are always those who want to use the goods provided by the state without paying for them. This behavior of taxpayers unbalances the state budget as the tax revenue collected becomes less than the expenditure. This leads to a budget deficit, and the remaining gap is filled with borrowed funds. Therefore, the goal of each country in the field of taxation is to create a tax system that would promote economic growth and ensure stable state revenues.

Tax avoidance is one of the most important problems facing all countries in the world today and accounts for a large enough share of the unaccounted economy. Tax avoidance can be equated with a tax gap, which indicates how much of the potential tax revenue the state does not collect into the budget due to one or another behavior of taxpayers. Most of the revenue to the state budget is collected from value added tax (VAT), but on the other hand, this tax is one of the most vulnerable, as there are cases of fraud related to the development of VAT schemes, concealment of part of turnover and falsified VAT invoicing, all unaccounted for sums of money for goods or services sold in order to reduce the VAT obligation. Therefore, it is important to know why taxpayers assume such behavior, what factors may lead to it. Once identified, the factors and causes of VAT avoidance can reduce the amount of revenue lost by the state. The problem of VAT avoidance is valid not only in the European Union but also worldwide, and the issue has not been investigated in detail due to data limitations, changes in calculation methodologies and the identification of complex causality.

The problem of tax and VAT avoidance in the world has been studied by many researchers (Ivaškaitė - Tamošiūnė, 2014; Giriūnienė, 2014; Bikas, 2019; Medelienė et al., 2011; Novošinskienė et al., 2007; Šinkūnienė, 2005; Keen et al., 2014; Borselli et al., 2012; Simionescu et al., 2016; Sasongko et al., 2019). Researchers emphasized that VAT is one of the main parts of tax revenue to the state budget, therefore, its collection is very important for the welfare of the state, but unanimous opinions and detailed analyses of VAT avoidance, what affects the VAT gap, what factors shape this tax avoidance behavior is missing.

The aim of the article is to analyze the factors influencing the VAT gap in the Baltic States.

The analysis and systematization of scientific literature, legal acts and statistical data was performed during the while analyzing the avoidance of tax and VAT avoidance. Based on the collected data, the analysis of the factors influencing VAT collection in the Baltic States is performed. Regression models of the Baltic States have been developed, with the help of which the main factors influencing the VAT gap in the Baltic States are mathematically expressed.

2. Theoretical background

Without taxes, modern society would not be able to survive, but despite state laws and regulations, there are people trying to avoid paying taxes. The optimal level of public goods provided by public authorities is only achieved when each taxpayer is honest and pays a part of his or her tax liabilities (Batrancea et al., 2012; Čižo et al., 2020). Franzoni (2000) identifies four basic rules that a taxpayer must follow in order to execute tax laws honestly:

1. Notify the tax authorities of the actual tax base;
2. Calculate the tax liability correctly;
3. Return the tax declaration on time;
4. Pay the amounts of money on time.

If at least one of these rules is violated, the taxpayer becomes ineligible, and non-compliance with the requirements also leads to tax avoidance.

Vasiliauskas (2005) names the concept of tax avoidance as, an violation of rights in order to obtain a tax benefit, which is understood as tax reduction or non-payment of taxes (using tax law provisions or reliefs), trying to create special tax conditions, to simulate a business model and thus obtain tax benefits. According to Paulauskas (2006), this behavior is called the most intelligent violation of tax laws. A taxpayer consciously evades tax obligations or reduces taxes without violating established legal acts, but his actions are contrary to the meaning of the law. These concepts are also supported by Palijanskas (2003), who describes tax avoidance as a taxpayer's activity aimed at "circumventing" the provisions of the law by formally following the established procedures without violating them. The concept of tax avoidance is complemented by James et. al., (2002) that tax avoidance considered a legitimate act of taxpayers because it is the application of loopholes in legislation system to reduce taxes. Tax avoidance includes not only the reduction of the tax burden, but also obtaining other tax benefits: deferral of the tax payment term, increase of the overpaid (deductible) tax overpayment (difference) and shortening of the tax overpayment (difference) reimbursement of taxes (Paulauskas, 2006). It can be said that tax avoidance is the legal action of taxpayers to take advantage of loopholes in legislation to reduce or avoid paying taxes. Tax avoidance is the main problem faced by the state in order to collect as much tax revenue as possible to the budget.

The willingness to avoid taxes is widespread in all countries of the world. According to the European Commission, EU Member States lose billions of euros in VAT revenue every year due to tax fraud and an inadequate tax collection system. The VAT gap, which is the difference between the estimated VAT revenue and the VAT actually collected, anticipates the loss of revenue because tax fraud, tax evasion and tax avoidance, but also due to bankruptcies, financial insolvency or loss-free calculation. The VAT gap is calculated by comparing actual VAT receipts with theoretical VAT liabilities (Reckon, 2009).

Compared to other misuses, VAT avoidance and evasion causes the greatest financial loss. The damage done to the states is particularly significant when in companies avoid VAT being paid internationally, when dozens of companies are involved in criminal activities in different countries of the European Union. By making fictitious transactions between themselves, companies seek to avoid paying VAT in some countries and to recover it fraudulently from national budgets. The German Ministry of Finance (2018) complements the range of forms of VAT avoidance and evasion from undeclared and/or unpaid VAT to the unfair right to use deductible input tax, known as 'carousel' VAT fraud. When dishonest unscrupulous suppliers collect large amounts of VAT from their customers and disappear before the tax authorities check the taxes.

In addition, the EU's fight against VAT fraud and avoidance considered the most important objective in the development of new EU legislation. Walpole (2014) argues that VAT avoidance and evasion involves a number of activities that deprive the state's treasury of the revenue will need to be collected legally. Unlike other taxes, VAT has two distinct areas in which taxpayers can target their fraudulent activities: they cannot only manipulate their liability for VAT, but can also abuse the purchase of VAT recovery mechanism, which is a way of using public funds.

In order to combat VAT avoidance, it is appropriate to identify factors that may influence taxpayers' behavior. There are many studies in the scientific literature which provide different opinions and identify the main factors influencing tax avoidance in different countries, but there are only a few studies that analyze VAT avoidance. Kiri (2016) states that the tax rate, audit probability, and the amount of the fine are the main factors influencing the level of tax avoidance. In addition, analyzing secondary sources, the authors found out that in some countries, the rate of tax avoidance decreases with increasing tax rates, while in other countries the opposite effect may occur. The results of the research differ because each country has its own specific characteristics. A study conducted by Richardson (2006) who evaluated data from 45 countries showed that non-economic factors have the greatest impact on tax avoidance compared to economic factors. The regression analysis results indicated that the less complex the taxes are and the higher the education of taxpayers is, the lower is the level of tax avoidance in all countries. The dependence on the unemployment rate and tax avoidance is emphasized by Lisi (2012). The author points out that a company's decision to avoid taxes depends on trust in the institution of tax administration, and it influences one of the most important macroeconomic variables i.e. the unemployment rate. Pomnerehme et al. (1996) analyzed Swiss data in order to determine taxpayer avoidance responses to changes in tax rates. The authors attributed to the dependent variable the difference between the declared income of taxpayers and national accounts data. The authors attributed average marginal tax rates, audit probabilities, and other indicators as independent variables. The results of the regression analysis showed that the relationship between marginal tax rates and tax avoidance is positive and statistically significant. According to Fisman et al. (2001) 1 percentage point increase in tax rates leads to 3 percentage point increase in tax avoidance.

Therefore based on the analyzed scientific sources, it was observed that tax collection and VAT are analyzed by various quantitative and qualitative methods. Many Lithuanian and foreign authors studied different aspects of tax and VAT avoidance, therefore, the research methodology is based on the scientific publications and research made by the following authors: Keen (2012) - examined the importance of tax collection in developing countries, Marandul et al. (2015), Itashiki (2011) and Bame-Aldred et al. (2011) were, interested in taxpayers' behavior, their values and sought to find out the reasons and connections that determine people's choice to avoid taxes, Bikas et al., 2020 assessed the impact of some variables on the VAT gap in Lithuania. Keen et al. (2014), examined VAT tax and its collection in the European Union countries, Borselli et al. (2012) analyzed the factors which reduce the ability to collect as much VAT revenue as possible to the state budget.

Summarizing, it can be said that studies produced in different countries show, that taxpayers' behavior in tax avoidance affects different factors in each country. Studies reveal that in some countries the effects of certain factors differ from other countries. It only proves that it is very important to single out the main factors influencing VAT avoidance. Based on the analyzed scientific literature and methods, it was chosen to analyze the VAT tax gap in the Baltic States and to investigate the factors that influence the VAT tax gap.

3. Research objective and methodology

In order to assess the impact of individual macro factors on VAT collection and the gap, the method of correlation regression analysis was chosen. According to Pabedinskaitė (2009), this method is widely used in social, economic and physical sciences while investigating various phenomena. Correlation regression analysis helps to determine the relationship between the variables under consideration and their interaction. Correlation, in this case, describes the strength of a relationship between variables, and regression analysis helps to determine the nature of that relationship and to describe the dependence of the mean values of a dependent variable on one or more independent variables using mathematical formulas. The result of the research is a regression equation, which shows the relationship between the factors and answers the question of how the average value of the examined economic phenomenon changes due to the factors on which it depends.

Correlation regression analysis consists of several important steps. It is determined which independent variables have the greatest impact on the dependent. A regression analysis is performed, during which regression equations are formed, which describe the relationship of the dependent variable with each independent variable individually. Correlation regression analysis is performed, which covers all the most significant factors previously selected. A multiple regression equation is also mode, showing the direction and strength of the effects of the factors under consideration (Pabedinskaitė, 2009).

A linear multiple regression model was used to the study, as the influence of many factors on the phenomenon under study investigated. The sum of the effects of all these factors will form the total influence on the phenomenon under consideration, and the influence of each individual factor, which is called partial, will be determined assuming that the values of other independent variables are constant (Krikštolaitis, 2007).

Three Baltic countries are analyzed - Lithuania, Latvia, Estonia. The choice of these countries was determined by the similar economic and social level of the countries and their regional policy.

The constructed models belong to linear multiple regression models because they are dependence equations having more than one independent variable. The purpose of the regression model is to quantify the impact of selected factors on the VAT gap. The influence of factors is estimated on the basis of regression model coefficients, which are calculated during the modeling process. Thus, regression models for all three Baltic countries will be developed to mathematically assess the factors influencing the VAT gap. For the regression models, a 95% confidence interval for the interval estimates was chosen, which indicates that 5% error is possible.

In the regression equation, the independent variables were chosen based on the potential risks and impact on VAT. The selected factors are adapted to the Baltic market, i.e. the same factors are analyzed in Lithuania, Latvia and Estonia. Eight variables were selected for analysis and included in equation (1). The VAT rate was used only in the Latvian regression model, because only in Latvia did the VAT rate change during the period under review.

$$Y_{\text{VAT gap}} = \beta_0 + \beta_1 X_{\text{GDP}} + \beta_2 X_{\text{consumption}} + \beta_3 X_{\text{VAT rate}} + \beta_4 X_{\text{average wage}} + \beta_5 X_{\text{burden of taxes}} + \beta_6 X_{\text{inflation}} + \beta_7 X_{\text{unemployment rate}} + \beta_8 X_{\text{migration}} + \varepsilon, \quad (1)$$

The resulting equation is evaluated by the selected variables. One of the criteria is "ANOVA". This is a summary of the Stjudent t criterion for several independent samples. This indicator shows whether there is at least one statistically significant variable in the obtained model (Bekešienė, 2015). The ANOVA p-value must be less than

0.05. Stjudent's t criterion is applied to independent samples when we want to compare the average of independent groups. If the corresponding p-value is <0.05, it means that this variable must be eliminated from the equation. One of the most important characteristics of the suitability of the model is the coefficient of determination (R-square). It shows the part of the variation that is explained by the model. A regression model with R squared <0.25 is considered inappropriate. It also cannot said based on this coefficient, that the model is appropriate for the data available. However, the higher this coefficient is, the more accurately it is possible to calculate the dependent variable from the independent ones (Bekešienė, 2015).

The research method is used to examine the dependence of the VAT gap on its determinants, which will also reflect tax avoidance, and the factors that cause it. This will provide to answer to the main question of the study - what factors and what influence do they have on the VAT gap in the Baltic States? The data on the VAT gap in the Baltic States are collected and processed on the basis of the study on the VAT gap in the EU countries conducted by the European Commission CASE (2019). VAT data is the period of 2012 - 2018, on the basis of which the difference between the theoretically planned collections of VAT revenue collection the amount to the budget, i.e. VAT gap. Other data required for the survey are collected and processed using the database of Statistics Lithuania and the database of the Statistical Office of the European Union - Eurostat. It was chosen to study the quarterly data of 2012 - 2018 in order to obtain more representative survey results. The regression models of the Baltic countries were created applying Excel program.

4. Results and discussion

Three Baltic States - Lithuania, Latvia and Estonia were selected for the study. These countries were chosen because of the similar level of economic development of neighboring countries, similar statistical indicators and VAT rates (Table 1).

Table 1. Statistics of the Baltic States (2017)

INDICATOR	LITHUANIA	LATVIA	ESTONIA
Population	2 827 947	1 944 565	1 305 755
Area	65 300 km²	64 589 km²	45 226 km²
GDP (nominal)	$48 132 bn.	$20 101 bn.	$16 410 bn.
GDP (nominal) per capita	$16 709	$15 613	$20 170
Gini coefficient	36	37,7	34
Human Social Development Index (HDI)	0,862	0,855	0,86
VAT rate	21%	21%	20%

Source: Lithuanian Statistics database

Statistics from the Baltic States show that all countries are similar not only in terms of population and area, but also in economic indicators.

The object of research selected for linear regression analysis (dependent variable is: Y - VAT gap and eight independent variables X - Gross domestic product per capita, value added tax rate, average earnings (gross), household consumption from GDP, tax burden, inflation, unemployment in the country and migration, which can affect VAT gap.

The VAT gap is calculated by deducting from the planned amount of VAT to be collected the actual amount of VAT that has been collected to the state budget (2).

$$\text{VAT gap} = \text{VAT}_{plan} - \text{VAT}_{fact} \text{ (2)}$$

It should be noted that the largest VAT gap in the Baltic States in the period 2012 - 2018 was in Lithuania, it ranged from 200 to 300 million Euros (Figure 1). Lithuania lost such amounts of money on a quarterly basis in the period of 2012-2018. The smallest VAT gap prevailed in Estonia, from 25 to 80 million Euros, which is three times more than the VAT collected in Lithuania. The Latvian VAT gap compared to Lithuanian and Estonian results is average it ranged from about 60 to 160 million Euros. On this basis, it can be said that this is probably the most volatile fluctuation of the VAT gap, which started to decrease quite rapidly since the second quarter of 2012, and that more and more VAT was collected in each quarter of the period under review.
Figure 1. VAT gap in the Baltic States in 2012-2018 (compiled by the author based on the data of the EC survey (2019)

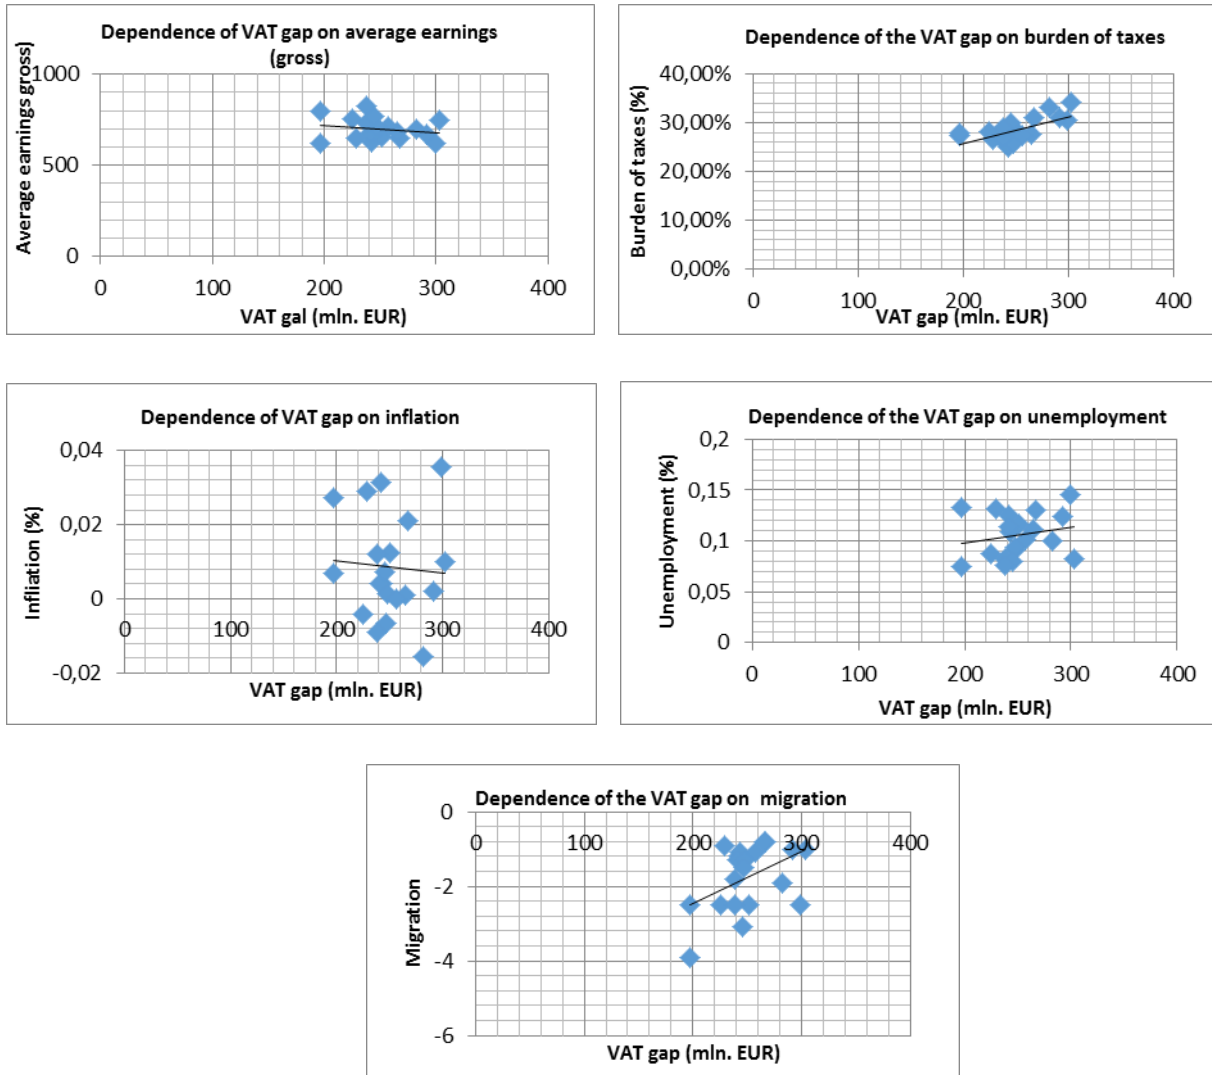
Lithuania is the first Baltic country chosen for the study. After systematizing all the quarterly data of the dependent variable and the independent variables for 2012–2018, the scattering of the values of the dependent variable is analyzed and the relationship between the variables is graphically represented before the initial regression equation is made. The values of the dependent variable are plotted on the vertical axis and those of independent factors are on the horizontal axis (Figure 2).


Figure 2. Dissemination of dependent and independent variables in Lithuanian

The obtained results showed that the increase of GDP per capita has a positive effect on the VAT gap in Lithuania, when the GDP increases, the VAT gap decreases and vice versa. The data are very unevenly distributed, so it can be concluded that household consumption does not affect the VAT gap. The average wage does not have a significant impact on the VAT gap, but the tax burden increases when the tax burden increases, and the VAT gap in Lithuania increases too. Inflation, like the unemployment rate, is not significant for the variable under discussion, and the data are unevenly distributed. However, migration is significant because the VAT gap narrows as migration increases. The initial regression equation (3) is constructed and obtained:

$$Y_{VAT\ gap} = 4,6910 - 0,0075X_{GDP} + 0,0543_{consumption} - 0,1714X_{average\ wage} + 9,7627X_{burden\ of\ taxes} + 0,3012X_{infliation} + 0,0920X_{unemployment\ rate} - 1,3635X_{migration} + \varepsilon \qquad (3)$$

The coefficient of determination is checked, which shows the percentage significance of the selected factors of VAT gap. The higher the value of this coefficient, is, the data fit the selected model better. The coefficient of determination of the initial regression model of Lithuania is 0,682467. It can be said that the significance of this regression model is sufficient for the analysis. The ANOVA p – value is also checked, it shows whether the value of at least one independent coefficient is statistically significant with the dependent variable Y. In the case of Lithuania, the value of p is equal to 0,009. If p <0.05, it can be stated that some factors exist which are related to the dependent variable in the model. In the model p = 0,009 <0.05, on this basis it can be said that at least one factor which make impact on the VAT gap.

Solving the regression analysis task the question arises whether the independent variable X influences the change of the dependent Y. Theoretical T (test) statistics calculated, according to which it can be assessed the significance of other factors and in order to eliminate the least significant factors for the VAT gap. The theoretical value of T is 2.0484, and comparing the theoretical value obtained with the calculated values obtained by constructing a regression model in order to exclude the least significant factors. If the theoretical value of t is greater than the calculated value of t, the factor is significant and we leave it, but if the calculated value of t is greater than the theoretical value of t, then the factor eliminated. The factors are eliminated from the smallest to the largest corresponding the equation: t theoretical > │t is calculated. Based on the values of the T statistics, the significant factors are selected and the correlation is calculated.

The least significant factors for the Lithuanian VAT gap are following: household consumption expenditure (-0,9854); average salary (gross) (-0,5444); unemployment rate in the country (0,0078); inflation rate (0,0619). Having rejected excluding insignificant factors, the coefficient of determination (R square) was rechecked again. After elimination of the factors, the value of the square of R is 0,6735. The correlation of the remaining factors determining the Lithuanian VAT gap was checked. The correlation between the variables did not change after rejected of the insignificant factors, therefore, based on the obtained data, it can be stated that correlation between the VAT gap and GDP (-0,5731), tax burden (0,6499) and migration (0,4599) factors is very strong. After checking the statistical indicators, the final equation of the linear regression of the Lithuanian VAT gap is presented (4):

$$Y_{VAT\ gap} = 11,8037 - 0,0047X_{GDP} + 7,0425X_{burden\ of\ taxes} - 1,4282X_{migration} + \varepsilon \qquad (4)$$

The obtained results of the research indicate that the tax burden had the greatest significance for the VAT gap in the period of 2012 – 2018 i.e. if it increases by one unit, the VAT gap increase by 7,0425 times. Migration in the country is also a very important factor, if it increases by one unit, the VAT gap in Lithuania decreases by 1,4282 times and vice versa, and an increase in GDP per capita by one unit will reduce the VAT gap by 0,0047 times.

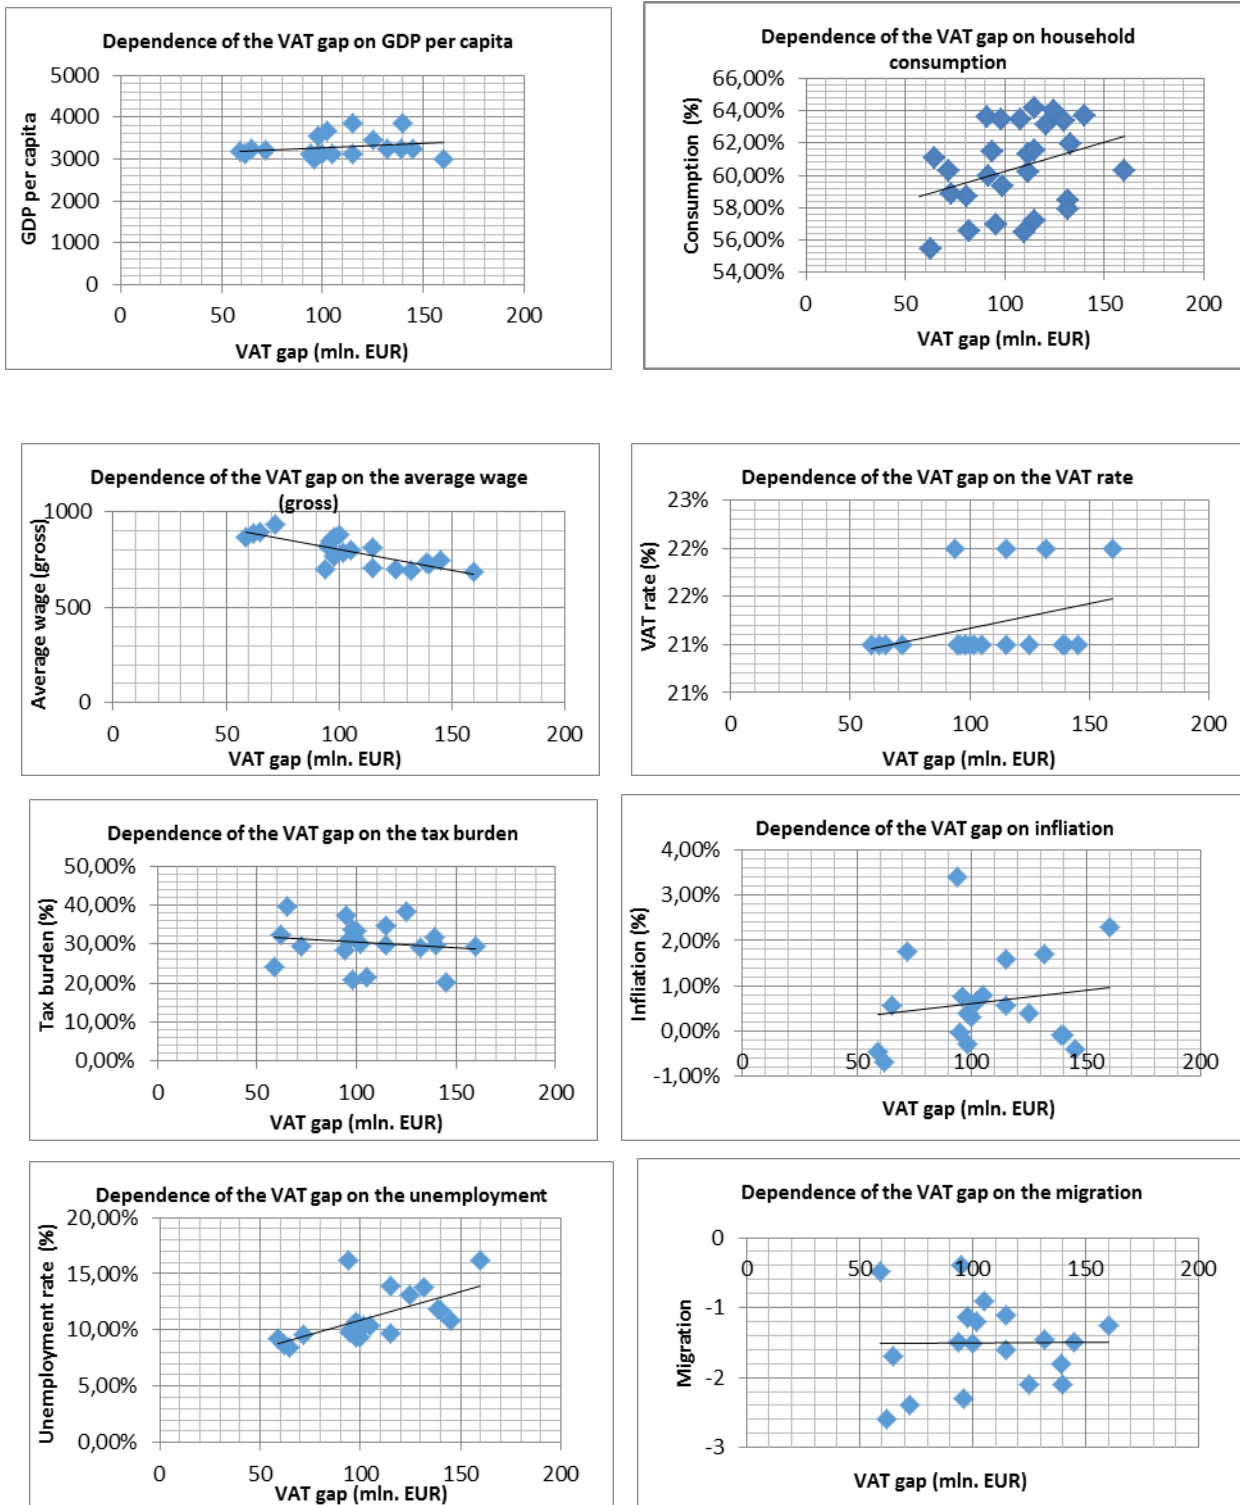
The next Baltic country to be analyzed is Latvia. Although it is said that the economies of the Baltic States are similar and their economic problems are similar, their solutions are often different, so the factors influencing them can be very different. The Latvian regression model is supplemented by another factor - the VAT rate. To tentatively estimate the dependence of the VAT gap, the dissemination of the factors (independent variables) and the dependent variable are compiled before the initial regression equation is constructed (Figure 3.).


Figure 3. Dissemination of dependent and independent variables in Latvia

The results show that in Latvia, GDP and migration indicators have a very small impact on the VAT gap. Household consumption has a minimal impact on the VAT gap, as the data are not trend-oriented. However, the growth of average wage has a positive effect on the VAT tax, the higher it is the smaller the VAT gap is. The relationship between the VAT rate and the tax burden is rather difficult to assess evaluate because of very uneven distribution of data. Inflation data are also very unevenly distributed, but there is the dependence which indicates that the higher the inflation is, the larger the VAT gap is. However, if the sufficiently even dependence of the VAT gap on the unemployment rate is, the higher is this indicator, and the wider is the VAT gap. The initial regression equation (5) is formed:

$$Y_{VAT\ gap} = 6,8840 - 0,0014X_{GDP} + 4,0865X_{consumption} - 0,2857X_{average\ wage} + 0,6708X_{tax\ burden} + 3,4048X_{infliation} + 2,8721X_{unemployment\ rate} - 3,4939X_{migration} + 1,7693X_{VAT\ rate} + \varepsilon \qquad (5)$$

The coefficient of determination of the initial regression model of Latvia, R square, is slightly higher than that of Lithuania 0,8174. The ANOVA p - value is checked, it shows whether the value of at least one independent coefficient is statistically significant with the dependent variable Y. In the case of Lithuania, the value of p is 0,022. Thus, in our model p = 0,022 <0.05, on this basis it can be stated that at least one factor influences the VAT gap. As in the Lithuanian regression model, there is need to check whether the independent variable X affects the dependent Y. At the initial level of the regression model, theoretical T (test) statistics is calculated, according to which the significance of other factors is evaluated and the least significant factors are eliminated. As the same error and the same amount of data applied to all countries, the theoretical value of t remains the same for all Baltic countries. Thus, the theoretical value of t is 2,0484. This theoretical value is compared with the calculated values and the factors are eliminated from the lowest to the highest value that do not satisfy this equation - t theoretical > │t. Based on the values of T statistics, the factors with the greatest influence are selected. The result shows that the tax burden, unemployment rate, inflation and migration have a minimal correlation with the VAT gap. After eliminating the insignificant factors, the coefficient of determination is checked again. The square of R is equal to 0,7954. The coefficient of determination decreased slightly with the removal of insignificant factors 0,7954 < 0,8174. Based on the obtained data, it can be said that the strongest link between the Latvian VAT gap is with the average wage (-0,7909), the VAT rate (0,3494) and GDP (-0,2064). Final equation for linear regression of the Latvian VAT gap is (6):

$$\mathbf{Y_{VAT\ gap} = 7,4088 - 0,0054X_{GDP} - 0,3470X_{average\ wage} + 1,6070X_{VAT\ rate} + \varepsilon} \quad (6)$$

Summarizing, it can be stated that the Latvian VAT gap is influenced by GDP, average wages and the VAT rate. However, the VAT rate is of the most importance. If the VAT rate increases by one unit, the VAT gap will increase 1,6 times, if the average wage changes by one unit, the VAT gap changes by 0,3470 times, and if the GDP unit increases by one unit, the VAT gap decreases by 0.0054 times.

The next Baltic country under investigation is Estonia. This country in 2012 - 2018 had the smallest VAT gap from the Baltic States. Therefore, it is important to find out what factors are most important for the VAT gap in this country. Before constructing the initial regression model, we identify the dependences of the dispersion of the VAT gap on the factors are identified so their interdependence can be assessed tentatively (Figure 4).

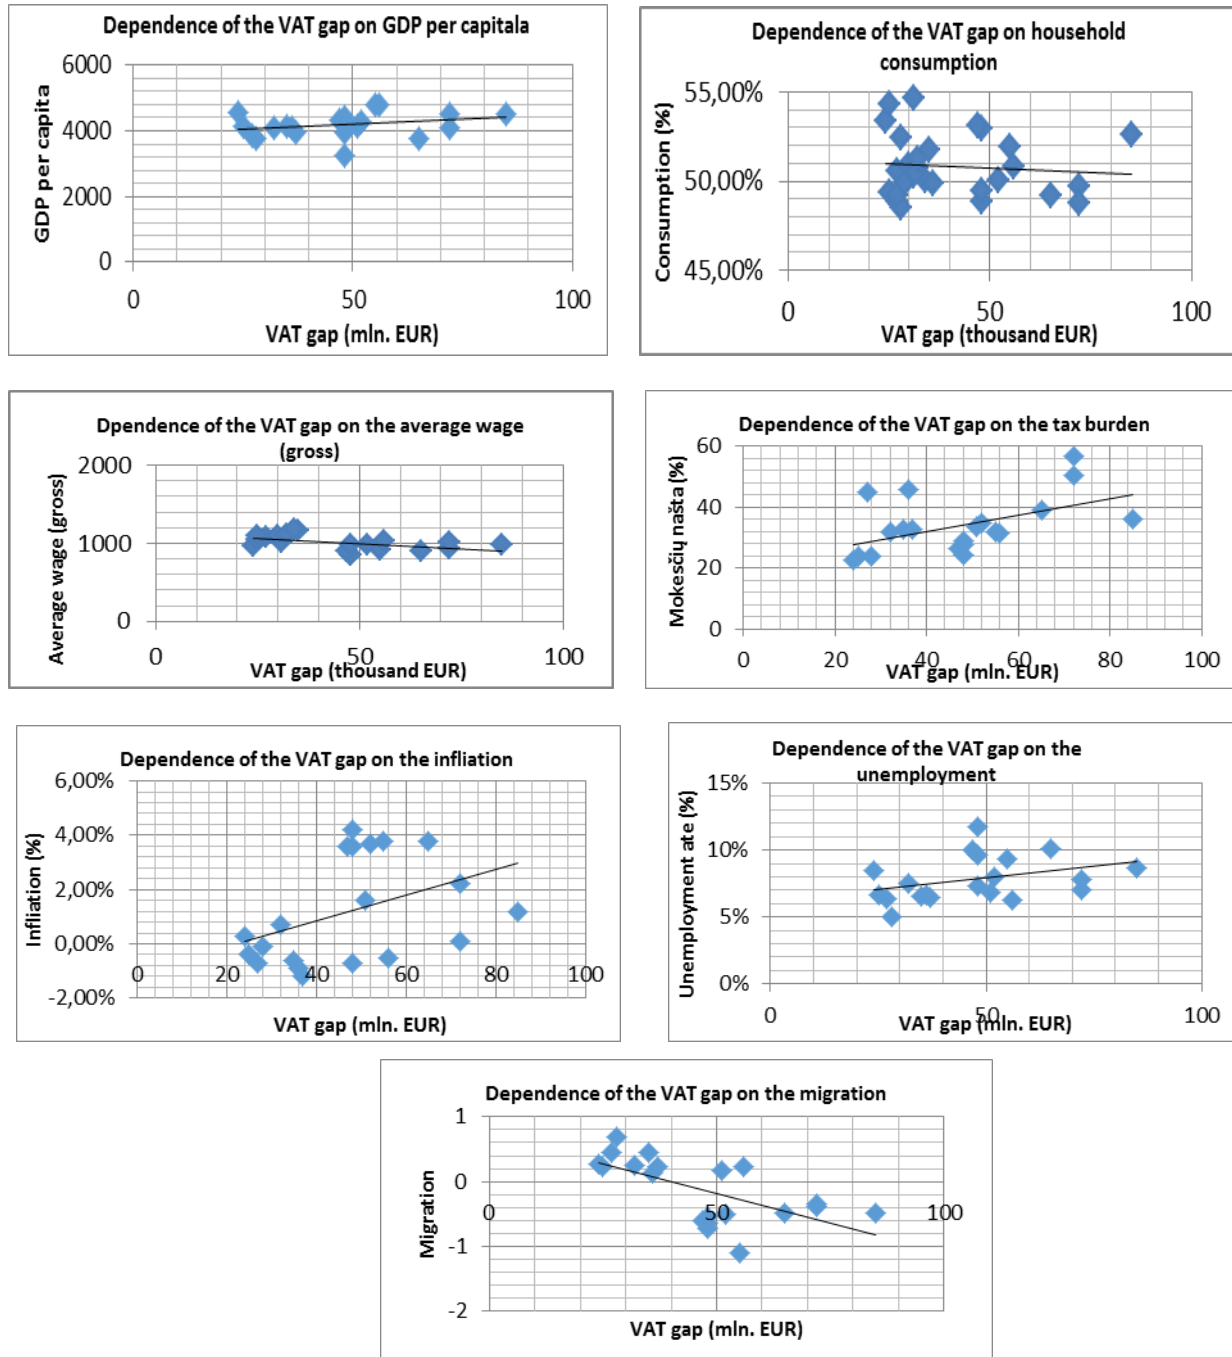

Figure 4. Dissemination dependent and independent variables in Estonia.

The results indicate that the dependence of GDP data on the VAT gap is very inconsistent. The GDP indicator does not make a significant difference to the VAT gap. The higher the average wage in Estonia is, the lower the VAT is, therefore, this factor may be significant for dependent variable. The increase in the tax burden, as well as in

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810

inflation, widens the VAT gap. The VAT gap is negatively affected by the unemployment rate, and as it increases, the VAT gap increases too. The positive value of migration clearly reduces the VAT gap and the negative one increases it.

After the preliminary factor dependence analysis, the initial regression equation is formed (7):

$$Y_{VAT\ gap} = 17,6220 - 0,0097X_{GDP} + 2,4102X_{consumption} - 0,0277X_{average\ wage} + 0,8508X_{tax\ burden}$$
$$+1,5912X_{infliation} + 2,0864X_{unemploydment\ rate} - 1,6109X_{migration} + \varepsilon \quad (7)$$

The coefficient of determination (R square) is checked, which helps to find out the suitability of the data for our chosen model. The coefficient of determination of the initial model of Estonian regression is obtained at 0,7513, i.e. smaller than in Latvia, but similar to Lithuania. Based on the value of the coefficient of determination, it can be said that our data are suitable for this model and it will be significant enough. The ANOVA p – value is also checked, with the help of which is defined whether the value of at least one independent coefficient is statistically significant with the selected dependent variable Y (value added tax gap). In the case of Estonia, a p-value is 0,0002, i. p = 0,0002 <0,05, it can be said, that at least one selected factor influences the VAT gap. The theoretical T (test) statistics of the regression model is calculated, according to which the significance of other factors is evaluated and the least significant factors are eliminated. The theoretical value of T is 2,0484. Excluding insignificant factors, it can be said that the factors influencing the VAT gap in Estonia are as follows: average wages (gross), the tax burden in the country and migration. After eliminating the insignificant factors, the coefficient of determination is checked again, where the square of R is 0,7043. The R square factor decreased slightly to 0,7043 <0,7513. Correlation analysis shows that the strongest correlation between the VAT gap is with average wages (-0,5832) and migration (-0,6342). Thus, after examining the key indicators, the final equation for the linear regression of the Estonian VAT gap can be presented (8):

$$\mathbf{Y_{VAT\ gap} = 17,6168 - 0,0013X_{average\ wage} + 1,8300X_{tax\ burden} - 0,6521X_{migration} + \varepsilon} \quad (8)$$

As it has been mentioned, according to the data of the EC VAT gap survey (CASE, 2019), the largest VAT gap in 2012-2018 was in Lithuania and the smallest in Estonia. The data on the Latvian VAT gap is between Lithuania and Estonia, but the data was much closer to Estonia, which shows that the VAT gap was not as big as in Lithuania. From the obtained Baltic regression models it can be stated that the indicator of GDP per capita in the analyzed period had a significance only for the Lithuanian and Latvian VAT gap, but very insignificant, as the coefficients for these variables are very small 0,0047 and 0,0054, respectively. The average wage depended on VAT gap also to a very small extent only in Latvia and Estonia. There were two factors that had no effect on the VAT gap in all Baltic countries: inflation and the unemployment rate in the countries. The VAT rate was used as an independent variable only in the Latvian regression model, because only in Latvia there was a change in the VAT rate during the period under review. The study showed that the VAT rate is a significant factor in the VAT gap, and as the rate in Latvia increases, so does the VAT gap. And the last two factors that were among the most influential in Lithuania and Estonia during the period under review were the tax burden and migration in the country. As the tax burden increased, it also widened the VAT gap quite significantly. Similarly, when the migration rate was positive (with more arrivals than departures), the VAT gap narrowed, and when it was negative (with more departures than arrivals), the VAT gap widened.

Summarizing all the factors determining the VAT gap, it can be divided into significant, less significant and insignificant factors. The greatest significance of the Baltic VAT gap is the tax burden, migration, and VAT rate. Among the insignificant ones are GDP and average wages, and the factors that are insignificant for the VAT gap in

the Baltic States were inflation and the unemployment rate in the country. On the other hand, the study revealed that all Baltic States needs to review their common tax policy, assess the tax burden and the standard VAT rate in order to reduce the VAT gap and VAT evasion.

Conclusions

The VAT gap provides for a significant loss of revenue due to tax evasion. The Baltic States 2012 - 2018 lost 11.5 million euros during the period. VAT revenue due to tax avoidance, tax evasion and inadequate tax collection systems.

The study showed that the tax gap, migration and VAT rate factors had the largest impact on the VAT gap in the Baltic States. Less significant factors were average wages and gross domestic product, while insignificant factors were household consumption, unemployment in the country and inflation.

The study showed that in Latvia, the VAT rate is a significant factor in the VAT gap, as the tax rate increases, so does the VAT gap. In Lithuania and Estonia, a significant factor in the VAT gap is the tax burden. The growing tax burden poses problems for tax evasion.

Abstract. The global economy and worldwide open market of goods and services creates a favorable environment for expanding technological cooperation among countries. However, such development is also accompanied by an intense movement of the labor force. After opening the EU single market, a large number of foreign workers from the new member countries found the better paying jobs in the highly developed EU countries. The total volume of this financial compensation that was transferred into mother countries was more than USD 70 billion in 2017. A primary question for this situation is the role that these financial sources play in the economies of the mother countries. Have the transferred money contributed to economic growth or have they been materialized in the sphere of private household consumption? Our paper answers these questions in the case of the Visegrad (V4) countries. The scientific literature does not offer a unified position in this respect. The positive, neutral, and negative impacts on concerned economies are presented. In our view, the answers should be verified in the specific conditions of the beneficiary countries, taking into account all the statistically relevant factors. The primary source of our information is statistical data of international organizations, particularly of the United Nations (UN), the World Bank, the Organization for Economic Cooperation and Development (OECD), the European Union, and the International Organization for Migration. As a tool for solution was applied the analysis of panel data.

Keywords: foreign direct investment; portfolio investment; economic growth; GDP; unemployment; regional development

---

1. Introduction

The global economy and worldwide open market create a favorable environment for expanding technological cooperation among countries. However, such development is also accompanied by an intense movement of the labor force. Consequently, the flow of financial remittances paid to the foreign labor force became an interesting topic for research and scientific studies. The cardinal question is whether the remittances received by an individual country have an impact on the country´s GDP growth.

After the opening of the EU single market, a large number of foreign workers from the new EU member countries found better paying positions in the highly developed EU countries. The total volume of such financial compensation transferred was more than USD 70 billion in 2017. According to valid data on the labor force movements, the large share of these financial means was transferred into the new EU member countries.

Faced with this situation, we raise the following question: what role did these financial sources play in the economies of the mother countries? Did these financial sources contribute to economic growth, or had they been materialized in the sphere of private household consumption?

Searching for the generally accepted answer is not an easy task, having in mind the large differences in volume of remittances transferred, the level of economic and social development in the receiving countries, the quality of transferring institutions and of the entrepreneurial environment, and the possibilities for investment of the external finances in the mother countries.

The main objective of this article is to verify the hypothesis on the impact of the remittance inflows on economic growth in the mother countries. For verification of the above hypothesis, we used econometric modelling, particularly the panel data analysis and Granger causality testing. The countries included in the study are the Visegrad Group (V4) countries: the Czech Republic, Hungary, Poland, and Slovakia.

We also use statistical data collected and processed by selected international organizations, particularly the United Nations, the World Bank, the Organization for Economic Cooperation and Development (OECD), the European Union (EU), and the International Organization for Migration (IOM).

2. Review of literature: migration and migrants

International migration, or the movement of people across the borders of countries, has historically occurred since ancient times and has happened for different reasons. While international migration has always had a major impact on the socio-economic environment or poverty alleviation in the countries of origin, it has also made an impact on the social and demographic structure of the targeted countries. Migration has influenced not only the economic but also the social and demographic environment of both host and parent countries.

The migration of humanity constitutes a special socio-demographic movement and has different forms, scopes, and durations as well as a considerably long history in virtually all parts of the world (www.historyworld.net). More recently, migration has been in the spotlight of the media and the professional public, as presented by Pooley (2019) and Hoerder. (2017)

According to Demirguc-Kunt (2019), the high degree of globalization in international and regional economies is one of the key factors that enhances interregional migration flows. Persistent differences in the income levels of the population as well as national and regional unrest and conflicts of war are also classified among the pro-migration factors.

Available statistics from the International Organization for Migration indicate that currently some 271 million people are living outside of their mother countries, which represents approximately 3.5% of the global population. More detailed statistical information on the reasons for this situation are found according to individual migration segments, including migrants, expatriates, clandestine migrants, immigrants, people who temporarily resettle, asylum seekers, and refugees, IMO (2020). However, the accuracy of statistics on migration flows, as highlighted by Alvarez (2015), is problematic to estimate.

The movements of residents from the mother country to the host country are referred to as migratory waves and are identified as immigration and emigration. The first case is represented by the "inflow" of people to the host country, and the latter case represents the "outflow" of residents from the parent country. The reasons for these movements may vary, as presented and analyzed by Castelli (2018); Consumer (2020); Filipek (2019); Hendricks (2019).

Generally, the migrants who leave the mother country tend to look for an opportunity to improve their personal and family economic and social situation. These migrants are classified as economic migrants. The main objectives of their migratory movement are mostly to seek countries with a higher level of economic development, a higher standard of living, and the possibility of an official access to the labor market as well as subsequently to achieve full incorporation into the social environment of the new country Kováč,M.(2015), Vaysilova (2019). Globally, approximately 266 million migrants are currently statistically classified as economic migrants. Most of them have the opportunity to enter the labor market and to obtain the officially reported salary as a domestic labor force. The financial compensation of these migrants, after transferring to the home countries is known as remittances World Bank (2016),

Extensive information sources confirm that migrants are an important factor in the host country's economy. According Kosten (2018), "the migrants play a crucial role in the U.S.A. labor force". The study of the University of Pennsylvania (2016) also confirms the importance of "the active participation of migrants in technical innovation and intellectual creativity in various academic and research fields across the US economy."

According to UN Secretary-General A. Guterres (2018), "the managed migration is one of the most challenging but also a promising social movement and opportunity for enhancing the international cooperation across the industrial and developing countries."

3. Migration remittances: what do they bring our countries?

Evidence of the active participation of migrants in the economic development of host countries is found in the increasing volume of remittances that are directly related to their labor activity. According the World Bank (2019), the volume of remittances transferred to the mother countries in 2018 was over USD 689 billion, whereby USD 529 billion (76%) was transferred to beneficiaries in low-income developing countries. The high volume of reported financial transfers "become over time one of the important external sources of their economic growth". Similar conclusions are presented by other sources World Bank (2016), OECD (2020).

The published outputs indicate a wide range of the assessed impact of remittances on the economies of the mother countries, ranging from a highly positive evaluation to the lack of any impact. Some articles even identified remittances as "corruption inhibitors", and therefore, they should be classified as a negative factor in the economic environment.

In this article, we specifically address the impact of migrant remittances on the economies of the Visegrad Group (V4) countries. We compare the volume and economic efficiency of the received remittances in these countries with the results of selected studies for another countries. We also present the various positions on the evaluation of the role of remittances in the economic growth of selected countries.

Meyer and Sherab (2016) have studied the impact of remittances on economic growth using the panel data approach to assess six remittance-receiving Balkan countries during the period 1999–2013. Their final analysis confirmed that remittances have a positive impact on economic growth in mother countries.

According to Nita (2016) "the remittances in Romania also have a positive impact on the economic development of this country." A similar position about Romania´s experience is presented by Comes (2018) et al.. Simonescu (2019) demonstrates a more complex evaluation of remittances that indicates both positive and negative aspects of migration flows in the context of Romanian membership to the EU. According to Cismas et al., "the hypothesis that remittances has a significant influence on the Romanian economy was not validated, and the statistical data does not show a long-run neither a short-run influence or a Granger causality."

A slightly similar conclusion is presented by Rauser et al. (2018) who posit that the remittances have a positive impact on the economic development in Lithuania, Latvia, and Estonia.

A certain level of skepticism in the evaluation of the remittances impact is also presented by Sobiech (2019) who found that "remittances can foster growth, but the effect is significant only at low levels of financial development of the individual country." In line with many other authors, he also believes that the remittances play an important role in alleviating poverty at the household level.

The role of remittances in securing the durability of economic growth in developing countries was studied by Adams Mensah Klobodu (2016). He found that remittance do not have a robust impact on the economic growth in Sub-Saharan African countries. However, as a byproduct of his study, he identified the so-called "institutional linkages" of remittances, meaning that the growth effect of remittances is enhanced by a stable and democratic government. Another conclusion is offered by Coulibaly (2015) who notes that no strong evidence exists to support the view that remittances promote financial development in Sub-Saharan African countries.

A strong position on the short-term and long-term effects of remittances is offered by Barajas et al (2010). Their study relies on the analysis of the development of remittance flows between 1970 and 2004 for 84 countries. According to these authors, the remittances have poverty-alleviating and consumption-smoothing effects on recipient households. Furthermore, Azam (2016) highlights that migration and remittances have first-order effects on poverty. This finding is based on a study representing 39 countries of high-, middle-, and low-income countries across the world.

A more cautious stance in evaluating the effectiveness of remittances is upheld by Clemens (2016). Similarly, according to Chami et al.(2018), "remittances are essential to fight poverty, but they failed to identify the remittances' impact on economic growth". The authors also identified the accompanying negative effects of

remittances, which often "contributes to weakening the entrepreneurial activity of young people, relying on external sources" which means accepting the downsides of the "Dutch disease."

Several authors from developing countries have made valuable findings on the negative phenomena identified in the analysis of the remittance flows. Specifically, these studies have mentioned the phenomenon of corruption, which has been identified as an endogenous factor at various levels of the economic implementation of remittances. Muhhamad and Khairuzzaman (2013) have examined this problem through a data base for five countries of South and Southeast Asia for the period 1985–2011. Applying the econometric model, they "found the positive and statistically significant effects of FDI and workers remittances on economic growth"; however, the empirical results simultaneously demonstrate the negative and statistically significant impact of endemic corruption on economic growth.

An exact analysis of remittances and corruption was studied on panel data from 122 countries by Majeed (2016), who identified that "among the least corrupt countries, remittances do not appear to increase corruption but, among the most corrupt countries, it significantly contributes to growth of corruption behavior." These findings are quite understandable and could help to assess situation for the majority of central European countries as well.
An in-depth study on remittances and corruption was conducted with data from 127 countries by Tyburski (2014), who adopted the political economy methodology to analyze these two phenomena. He found that democratic institutions significantly reduce the probability that remittances increase corruption and that democracies tend to control corruption better than nondemocratic regimes. According the author, "the remittances should be considered as a curse but also as a cure for corruption." Another strong position about the outcome of remittance inflows is presented by Berdiev et al.(2013), who have also identified the existence of a negative institutional impact.

The fact that the published results evidently indicate a wide range of unsolved problems related to the inflow and outflow of remittances is important to underline. In particular, many articles draw attention to the ambiguous impact on the economies of the beneficiary countries. We follow this position when presenting our results.

4. Are there real causal relations between remittances and economic growth?

Furthermore, the published scientific findings that are unsure about making direct causal links between correlated variables deserve greater attention. Aldrich (2018) presents various scenarios of the inappropriate and incorrect application of the methods of correlation and regression analysis. The findings highlight the repeated errors in the methodologies of research projects and publications by arguing that "...correlation alone cannot be used as evidence for a causal-and-effect relationship between a treatment and benefit, a risk factor and a disease, or a social or economic factor and various outcomes."

An important position is presented by Kahn (2018), who notes that "causal effects are difficult to quantify because we rarely observe occasions, where one variable is changed while others are constant." Such methodological weakness have also been studied by Bleske-Rechek (2015) who underlined that little systematic data is available to the extent that individuals conflate correlation with causation. She also found that people frequently tend to draw causal outcomes from non-causal data, regardless of the statistical findings.

An noteworthy study of the correlation and causality phenomena is offered by Panizza and Presbytero (2014). They studied if public debt has a causal effect on GDP growth in OECD countries. According their findings, a

negative correlation exists between debt and growth. However, the link between debt and growth disappears after the researchers corrected the model for endogeneity.

The highly qualified approach to the problem of identification and differentiation between correlation and causal relationships has also been developed in biological science, as presented by Berwick (2017).

In conclusion, finding answers to questions about the impact of remittance payments on the volume or the growth of GDP and GDP per capita is more complex than it appears at first glance in light of the studies previously presented. To respond to the research topic properly, extending the model instruments in such a way as to eliminate the incorrect interpretations of correlation and causal relations is necessary.

5. Objectives of the article

The dynamic of migration movements in Czechia, Hungary, Poland, and Slovakia are the subject of sharp political and expert discussions in these countries. In particular, the financial flows that represent compensation are closely monitored for migrant workers who operate abroad outside of their parent country. Given that these financial flows are mainly directed from industrialized countries to countries with a lower level of economic potential, they are analyzed not only in terms of their volume but also in terms of their potential impact on the dynamics of the economy of the parent countries whose citizens are the beneficiaries of these means. For many countries, the volume is comparable to the volume of external financial resources such as the official development assistance (e.g., Official Development Aid or ODA) and direct foreign investment (e.g., Foreign Direct Investment or FDI). Therefore, the question under investigation is whether these resources have a positive impact on the dynamics of the growth of the national economy, namely the economies of the countries to which the remittances are directed.

Based on the literature, we segmented the arguments and conclusions into the following groups:
1. Tne first group of authors presents conclusions on the **clear positive impact** of remittances on the economic growth of the beneficiary countries. These positions are based on model projections, in which the volume of remittances is identified as one of the statistically significant explanatory variables.
2. Based on similar model instruments, another group of authors offers **more cautious conclusions** on impact of remittances on GDPpc. The effect of remittances is presented as accompanying phenomenon with the other development assistance sources. Also, the statistical significance of the REMIN confirm to this conclusion.
3. Another group of authors rejects the general conclusions on the positive impact of remittance on economic growth of the beneficiary countries. These authors, based on more sophisticated modelling analyses, highlight the negative effects on the corruption environment which is detrimental to the home economies. Important warnings exist also about the insufficient verification of the causal effects of remittance on economic growth.
4. Interesting results are presented by authors who highlight the institutional aspects of the environment in which remittance inflows are materialized. The quality and efficiency of relevant government institutions and their democratically functioning structures and processes are pointed.

The main objective of our paper is to verify the remittance inflows and other relevant factors in terms of their impact on economic growth of the V4 countries. We have used model tools and information sources that have been applied in the majority of published and analyzed articles. Adopting this approach, we intend to eliminate the impact of different methodologies in quantitative analysis and to increase the comparative weight of our results.

6. Methodological framework

The impact of remittance inflows and other selected factors on economic dynamics is estimated through the GDP per capita volume and the GDP per capita growth.

The general econometric model on basis of which we analyze the dependency in question takes the form of the following:

$$Yi = \alpha + \sum_{j=1}^{n} \beta i X i + u = \alpha + \beta 1 * X1 + \beta 2 * X2, ..., \beta n * Xn + u \qquad (1)$$

where **Y** is the studied dependent variable, **α, β1, …, βn** are the regression coefficients, and **u** is the expected estimation error.

Model (1) is analyzed in two alternatives, where variable **Y** presents the following:
- Alternative A—Volume of GDP per capita   labelled as **GDPpc**
- Alternative B—Annual growth of GDP per capita   labelled as **GDPpc-G**

As explanatory factors, or independent variables, according to earlier conducted theoretical studies and experimental recounts, we have defined the following:

Factors	Variable	Label
1. Volume of inflowed remittances as % GDP	- REMIN	X1
2. Volume of inflowed remittances-lagged as % GDP	- REMIN-1	X1-1
3. Volume of outflows of remittance as % GDP	- REMOUT	X2
4. Export as % GDP	- EXPORT	X3
5. Import as % GDP	- IMPORT	X4
6. Direct foreign investment as % GDP	- FDI	X5
7. Total capital formation as % GDP	- GCF	X6
8. Total volume of final consumption as % GDP	- FINCONSUM	X7
9. Volume of international trade as % GDP	- TRADE	X8
10. Population growth in % annually	- POPUL-G	X9
11. Government debt as % GDP	- DEBT	X10

To eliminate the heteroscedasticity in values of dependent variables, we have used their log transformed values as follows:

- GDPpc   - new value   - **LN(GDPpc)**

The values of all explanatory variables are applied in their relative values toward the national GDP.
The values reflecting annual growth of GDPpc-G are presented in their relative values (%) toward the previous year.

The relevant statistical information for the V4 countries for period 2000–2018 is transformed into panel data, in which the specificities of each country are represented by sectoral, time invariant variables labelled as Czechia, Hungary, Poland, and Slovakia.

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810

On basis of an analysis of previous economic developments, the significant impact of the economic recession on individual national economies has been identified in the countries concerned in 2009 and 2010. To quantify this impact, we expanded the list of time invariant explanatory variables labelled as Crisis09 and Crisis10.

Having in mind the above presented clarification, the econometric model for estimating the theoretical values of the statistically dependent variable LN(GDPpc) and GDPpc-G has the following form:

For dependent variable LN(GDPpc):

$$LN(GDPpc) = b1*REMIN + b2*REMIN-1 + b3*REMOUT + b4*EXPORT + b5*IMPORT + b6*FDI + b7*GCF + b8*FINCOMSUM + b9*TRADE + b10*POPUL + b11*DEBT + u \qquad (2)$$

For dependent variable GDPpc-G:

$$GDPpc-G = b1*REMIN + b2*REMIN-1 + b3*REMOUT + b4*EXPORT + b5*IMPORT + b6*FDI + b7*GCF + b8*FINCOMSUM + b9*TRADE + b10*POPUL + b11*DEBT + u \qquad (3)$$

Consequently, we verified the applicability of both models to estimate the impact of remittance flows on macroeconomic indicators LN(GDPpc) and GDPpc-G. This means that we should verify the validity of the following hypotheses:

H1: Variable REMIN has a statistically significant impact on LN(GDPpc)
H2: Variable REMIN has a statistically significant impact on GDPpc-G

As a methodological tool to answer the above presented hypotheses, we applied the pooled regression models with the fixed effects.

As a final test for evaluating the impact of remittance inflows on economic growth, the Granger causality test was employed. According the EViews approach, this test is based on bivariate regression of the following form:

$$LN(GDPpc)t \quad = Yt = \alpha o + \alpha 1*Yt-1+...+ \alpha l*Yt-l + \beta 1*Xt-1+...+ \beta l*Xt-l + ut \qquad (4)$$
$$REMINt \qquad = Xt = \alpha o + \alpha 1*Xt-1+...+ \alpha l*Xt-l + \beta 1*Yt-1+...+ \beta l*Yt-l + ut \qquad (5)$$

where Yt and Xt correspond to variables LN(GDPpc)t and REMINt .

In the above formulated model (4), the Xt (REMIN) does not Grenger-cause Yt (GDPpc) only if all βj=0. Reciprocally, in model (5), the Yt (GDPpc) does not Grenger-cause Xt (REMIN) only if all βj=0.
Testing procedure was performed by EViews software package.

7. Data, results, and discussion

All input data are drawn from the World Bank, the International Organization for Migration, Eurostat, and the UN OpenData sources. The time series data of the relevant indicators for the 2000–2018 period is presented in Table 1.

The original data is organized in the form of a pooled panel data to sequence of Czechia, Hungary, Poland, and Slovakia. The sectorial, time invariant variables, Crise06 and Crise10, as well as the sectorial variables representing the individual countries of Czechia, Hungary, Poland, and Slovakia were added consequently. The descriptive statistics are presented in Table 2.

Table 2. Descriptive statistics of the original variables

Particular interest is focused on the values of correlation coefficients between the dependent variables LN(GDPpc) and the core studied explanatory variables of REMIN and REMOUT. Figure 1 presents the linear regressions between these variables under the pooled panel data scheme.
Fig. 1. Linear regression between LN(GDPpc) and REMIN, REMOUT
Source: World Bank, the authors
Fig. 2. Linear regression between LN(GDPpc-G) and REMIN, REMOUT
Source: World Bank, author

As expected, the analysis of data in the pooled form, without respecting the sectoral time invariant factors, demonstrates relatively low correlation ties (see Figure 2). However, a significantly different situation is presented if the data is analyzed for individual countries, as demonstrated in Figure 3.
Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810
Figure 3. Linear regression between LN(GDPpc) and REMIN for individual countries
*Source: W*orld Bank, the authors

The last figures present the need to adopt the panel data approach, with sectoral variables reflecting the country specificities.

With reference to the published findings, specifically those of Aldrich (37), Aisbett (38), Kahn (39), Panizza (41), neither high nor statistically significant values of the correlation indicators do not confirm the causal relationship among the considered variables. They only reflect their correlation closeness and this should be respected in interpretation of the results of following statistical analysis.

8. Remittances as a factor of economic growth in the V4 countries

In line with the methodology of this paper, the main factors to further monitor the volume and growth of gross domestic product per capita are the following independent variables:
- The inflow of remittances into V4 countries
- The outflow of remittances from V4 countries

According the officially reported data presented in Table 4, more than USD 613 billion was redistributed worldwide in 2017, which confirms the significance of monitoring and analyzing the remittance flows.

The total EU transfers amounted to USD 147 billion in 2017, of which USD 77 billion were directed to non-member countries, particularly to the low-income developing countries.

Table 4. Remittance flows between EU and non-EU countries

Remittance flows between EU and Non-EU countries			
Volume of remittance flows 2017, mil USD			
	EU	NON EU	Spolu
EU	70 290	77 691	147 981
NON EU	53 989	411 494	465 483
Total	124 279	489 185	613 464
Share of remittance flows, 2017, %			
	EU	NON EU	Spolu
EU	11,46	12,66	24,12
NON EU	8,80	67,08	75,88
Total	20,26	79,74	100

Source: World Bank, the authors

To clarify the current situation related to remittance flows and their expected positive impact on economic growth in selected EU countries, we present the statistical data on remittance inflows in the V4 countries for the 2000–2018 period, Figure 4a.
Fig. 4. Inflows of remittances into V4, mil. USD
Source: IOM, the authors

The highest share of remittances gained (as % of GDP) among the V4 countries was Hungary (3%), while the share of Slovakia´s remittances reached 2.1%. In Czechia and Poland, where labor markets have not been severely weakened over the studied period, the share of remittances was slightly lower with 1.6% and 1.3%, respectively.

Concerning the final destination of these finances, the households in Slovakia received total transfers in 2018 of more than USD 2.21 billion, and since 2004, the total was over USD 26 billion. Of this amount, more than 87% were transfers from EU countries, mainly the UK, Czechia, Germany, and Austria.

The V4 countries, as an organic part of the European Union's economic and social space, also created a wide scope for a foreign labor force that involves the subsequent financial compensation of foreign workers in the form of remittance outflows, as presented in Figure 4b.

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810
Fig. 4b. The remittance outflows from V4 countries, mil. USD
Source: IOM, the authors

The volume of outflow remittances was significantly lower than the volume of remittances received. In 2018, the volume of remittance paid in Czechia was USD 2.758 billion, USD 1.011 billion in Hungary, USD 7.094 billion in Poland, and USD 0.385 billion in Slovakia. In these countries, the share of the disbursement paid was 1.13% in Czechia, 0.656% in Hungary, 1.211% in Poland, and only 0.361% in Slovakia. The total volume of remittances paid in Slovakia for the entire period of 2000–2018 amounted to USD 2.3 billion.

The growth of the GDP per capita and the volume of remittance per capita is presented in Figure 5. While the development of GDPpc in the V4 countries follows a similar mode in economic growth with the leading position of Czechia and Slovakia, the inflows of remittances in these countries indicates a different pattern with leading positions for Hungary and Slovakia.

9. Solution of econometric models (2) and (3)

To confirm the initially formulated hypotheses H1 and H2, the models (2) and (3) and their solutions are presented. The dependent variables LN(GDPpc) and GDPpc-G are expressed through the set of explanatory variables defined earlier. The solutions of these models are presented under three scenarios and two forms.

The first scenario offers the pooled linear regression for estimating dependent variable LN(GDPpc). The explanatory variables are presented in Table 1.

Under the second scenario the dependent variable is estimated through expanded list of explanatory variables, where the time invariant variables representing individual countries are taken into account.

The third scenario considers also the expected external impact of economic crisis in 2009 and 2010 toward all studied countries.
All solution are presented in two form A and B. The form A contains all explanatory variables, while the form B contains only a list of statistically significant variables with p < 0.05 (see Table 5).

Source: IOM, the authors

Concerning the impact of remittance inflows, the variable REMIN is statistically significant according several versions of model (2). The highest level of reliability in explaining variability of dependent variable LN(GDPpc) is presented by Expanded model with time invariant variables representing individual countries and crises. The respective index of determination has a value of R2=0.936. The robustness of the model is presented by empiric and estimated time series data of LN(GDPpc), according the last presented model, Figure 6.

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810
**Fig. 6.** The empiric and estimated values of LN(GDPpc)
Source: the authors

The time-invariant sectoral and country related variables for Hungary = -0.3711 and Slovakia = -0.4356 indicate a fairly strong effect on the nationally specific factors to transfer the remittance inflows into economic growth. To identify them, the additional variability analysis of the values LN(GDPpc) would be required by introducing the relevant "hedonic variables."

All solutions to Model 3 (see Table 6) demonstrate slightly lower degrees of coherence among the empiric and estimated data. Total variability in GDPpc-G values is covered by the identified explanatory variables to maximum at 86% (respectively 77%). The empiric and estimated time series of GDPpc-G are presented on Figure 7.
Fig. 7. Time series of empiric and estimated values for Models 2A and 2B
Source: the authors

Based on the results of all presented models, the statistically significant impact of the remittance inflows on GDPpc volume and GDPpc-G growth of hosting countries was identified by both econometric models. Results obtained by these econometric models could be accepted as a confirmation of the working hypotheses, H1 and H2. In the economic interpretation, this finding means that remittance inflows in the Visegrad group countries (V4) during the period 2000–2018 had positive impact on economic growth measured by volume of GDPpc as well as on annual growth of GDPpc.

10. Granger causuality approach

The last step in evaluating the importance and validity of the impact of remittance inflows is the Granger causality test between variables LN(GDPpc) and REMIN and LN(GDPpc-G) and REMIN. The results are presented below in Table 7:

Table 7. Results of Granger Causality Testing for Model 2

Pairwise Granger Causality Tests Date: 06/30/20 Time: 23:15 Sample: 1 76 Lags: 2			
Null Hypothesis:	**Obs**	**F-Statistic**	**Prob.**
REM-IN does not Granger Cause LN(GDPpc)	**74**	**1.29680**	**0.2800**
LN(GDPpc) does not Granger Cause REM-IN		**4.05072**	**0.0217**

Source: Eviews, author

According the results above, we cannot reject the hypothesis that REM-IN does not Granger cause LN(GDPpc); however, we reject the hypothesis that LN(GDPpc) does not Granger cause REM-IN. This indicates that the Granger causality runs in the direction from LN(GDPpc) to REM-IN (see Table 8).

Table 8. Results of Granger Causality Testing for Model 3

Pairwise Granger Causality Tests Date: 06/30/20 Time: 23:31 Sample: 1 76 Lags: 2			
Null Hypothesis:	**Obs**	**F-Statistic**	**Prob.**
REM-IN does not Granger Cause LN(GDPpc-G)	**74**	**1.02770**	**0.3632**
LN(GDPpc-G) does not Granger Cause REM-IN		**0.83185**	**0.4396**

Source: the authors

In the case of Model 3, we cannot reject neither of the two hypotheses.

These findings are in line with the previous conclusions about the impact of remittance inflows obtained by econometric models (2) and (3).

All the results of the above presented econometric analysis and the Granger causality tests offer qualified information about the ties among the studied variables. However, the presented results have only partially confirmed the positive impact of remittance inflows on economic growth in the studied countries. Despite the high value of the obtained information, the final interpretation of the results, namely their transformation into terms of causality, should be considered in the context of all the relevant economic and social dimensions.

Conclusions

The worldwide globalization of economies, their technological openness, and their interconnection also amplifies the national labor markets and consequently, the migration of workers from less developed countries into labor markets that offer higher compensations. These financial means or remittances are private incomes of individual workers. However, because of their high volumes, these means are considered as a possible source of economic growth of national economies of the mother countries. For this reason, remittance flows between the hosting and the mother countries of foreign workers has been a frequently discussed topic in professional literature.

The main goal of our discussion was to answer the research questions that were formulated through the two working hypotheses. As a methodological tool, we adopted the panel data analysis supported by econometric model techniques and Granger causality testing.

On the basis of the statistical information obtained, formulating the following positions on the working hypotheses is possible:

Hypothesis 1:
A statistically significant impact of remittances received on the volume of LN(GDPpc) **has been confirmed** based on Models 2A and 2B.

Hypothesis 2:
A statistically significant impact of the remittances received on the growth of GDPpc-C has not been confirmed based on Models 3A and 3B.

We consider that all the above findings should be interpreted as results based on the correlation and regression relationships, which **do not provide sufficient arguments to confirm the generally valid positive causal relationship** between the remittance received and the dynamics of the GDP in case of the four Visegrad group countries.

IMPACT OF COVID-19 ON SMES AND EMPLOYMENT

Ahmad Al-Fadly

College of Business Administration, Gulf University for Science & Technology, Kuwait

E-mail: alfadly.a@gust.edu.kw

Abstract. COVID-19 is a highly infectious disease-causing serious health hazards and fatalities to humans around the world. The objective of this paper is to identify how COVID-19 caused immense failures to society, particularly Small-Medium Enterprises (SMEs) in the hospitality and tourism sectors which provide employment to many people. A literature review examined how preventive measures to control COVID-19 devastated businesses. The review highlighted particular interest to workforce, supply chain and cash flow of SMEs. This research addressed the gap in understanding what and how business was affected as seen by business owners. This research used phenomenology to study businesses crippled by the pandemic. Interviews were conducted with several business owners using a set of unstructured guiding questions. Verbal responses from the participants were transcribed to textual data and analyzed thematically. The results constructed a generalized perception of SME business owners and identified themes reflecting the business individual, the business, and business survival. Importantly, the study revealed several government actions are needed to support surviving businesses and revive lost businesses, specifically, in the form of stimulus funds, moratoriums, extended loans and waivers of interest.

1. Introduction

The pandemic COVID-19 crisis has negatively affected the hospitality and tourism industries in Kuwait by forcing Small-Medium Enterprises (SME) in Kuwait to curtail much of their businesses. On April 6, 2020, the Kuwaiti government extended curfew hours and imposed lockdown of certain areas (WorldAware, 2020). These new measures were a part of the government's effort to prevent the spread of COVID-19. But this also meant that public were banned from meeting in restaurants, cafes, and commercial centers. Intrinsically, this meant that outlets like coffee shops, restaurants, hotels and travel agencies had to close their doors until further notice. Together with earlier suspension of commercial flights to and from Kuwait, travel and tourism had already taken a plunge. Altogether, the preventive restrictions meant that inter-dependent businesses were collectively doomed

(WorldAware, 2020). Following from the extended curfew and lockdowns, SMEs started to feel the financial crunch caused directly by coronavirus disease. At least 45 % of Kuwaiti small business owners said they had suspended or shutdown their businesses while 26% were on the verge of collapse with revenues dropping more than 80 % (Bensirri Public Relations, 2020). Irrefutably, with the increase in the pandemic, many small businesses in Kuwait have become clueless about their future.

The problems faced by the SMEs is that COVID-19 has moved from a health crisis to an economic crisis. Business owners are fervently trying to survive both the crises almost certainly with lesser resources. Some sectors suffer more than others with accommodation, food service and travel being most hit (Skidmore, 2020). It is proposed that businesses undergo a four-phase process. First, businesses see a collapsing demand with a plunge in the cash received. Second, businesses see a dwindling of product and services necessary for business as the supply chains are increasing broken (for the same reasons). Third, remaining open under lockdown or partial lockdown situations posed new work conditions never experienced before. Face masks and social distancing although disruptive to human interaction have become essential. The lockdown also imposes intricate problems of workers travelling to and from work. Fourth, reduced workforce and movement control compelled small business owners to work with greatly reduce workforce (Skidmore, 2020; Besenyő, Kármán, 2020).

To put it in a statement, the plight of small business owners has not been heard from the victims themselves. The fragility of the SMEs is often assessed from business indices available from national statistics. Administration based on such statistics "failed to successfully choose, monitor, and keep track of how the young entrepreneurs managed their fledgling businesses" (Al Sharekh, 2018). Thus, it is essential to understand the voice of the business owners to better help them sustain or regain their businesses. The effect of COVID-19 needs to be comprehended from the literal voice of the small business owners themselves.

The aim of this study was to culminate in a credible comprehension and interpretation of the effect of COVID-19 on the collapse of Small-Medium Enterprises and failing employment.

1.1. Purpose of the Study
The purpose of this study was to explore the extent to which COVID-19 has affected SMEs namely, coffee shops, hotels, restaurants and travel agents. The study is scoped on the business individual, the collapsing business and anticipation of governmental assistance. The study examined the slew of factors hitting the business individual and how businesses managed to survive – literally from the disease and the grips of sustaining. It also explored the hopes and expectations of business to survive the pandemic with government initiatives.

1.2. Questions Guiding the Research
The study examined the perceptions of businesses affected by the COVID-19 pandemic. The phenomenological methodology allowed participants to express their own experiences and consequently the direction of the study. The participant expression was based on three guiding questions which provided the framework for this study:
1. How are individual business owners affected by the pandemic?
2. What are the main issues and their resolutions to bounce back by businesses?
3. What government assistance do business owners expect in bouncing of the pandemic?

2. Literature Review

COVID-19 also known as the Coronavirus is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). This is a new strain of infection that appeared toward the end of 2019. The virus was first identified in Wuhan, China and reported to WHO on December 2019. The virus spread rapidly across the globe and WHO declared the virus a public health emergency on January 30, 2020. On March 11, 2020 the virus was named COVID-19. By then it had spread to over 118,000 cases in over 110 countries that the World Health Organization (WHO) declared a coronavirus pandemic outbreak. This viral respiratory disease caused symptom that occurred after 1-14 days following exposure of an average of 3-7 days (WorldAware, 2020). The symptoms include fever, fatigue, cough, difficult breathing, sometimes worsening to pneumonia and kidney failure - especially in those with underlying medical conditions. The Coronavirus caused the COVID-19 pandemic which is part of a worldwide phenomenon. As of June 25, there were 485,707 deaths and 9,566,268 confirmed cases of the disease (World Health Organization, 2020).

There is currently is no vaccine available for treating COVID-19. However, symptomatic treated is provided by early emergency medical support. The control of COVID-19 requires drastic action that arrest the disease from spreading. COVID-19 spreads readily through symptomatic people to others who are in close contact. The virus is transmitted through direct contact with respiratory droplets arising from coughing and sneezing of an infected person. Individuals can also be infected from and touching surfaces contaminated with the virus and then touching their face (e.g., eyes, nose, mouth). COVID-19 virus may survive on surfaces for several hours, but simple disinfectants can kill it (UNICEF, 2020).

Unfortunately, the drastic measures required to prevent the spread of COVID-19 requires several legislated actions that prohibit the normal functioning of society. These include wearing face masks, social distancing, stay home and the ultimate lockdown of all movement. Consequently, normal business activities cannot be conducted for fear of spreading the disease. Most business have had to close their shops or malls resulting in a multitude of unprecedented issues. Closing shop means losing business and therefore losing revenue. This triggers a domino effect of issues forefront of which is employment and the welfare of the employees.

The closure of businesses means that many businesses are unable to operate and are closed down. Following the institution of lockdowns in Kuwait in March 2020, 45% of business owners indicated they have suspended or shutdown their business. A Kuwait COVID-19 business impact survey reported that a further 26% were about to collapse due to a revenue drop of over 80% (Bensirri Public Relations, 2020).

Among the industries, the demand for hospitality including, restaurants, hotels and travel has been high. Indeed, the hotel-restaurant-tourism industry are interlocked. Restaurants that were based on direct customer presence on-location have been hard hit. Similarly, hotels and tourism have been severely hit due to the inter-relationship between the industries. Cancellation in restaurant catering and hotel stay are in tandem with cancellation of planned trips with none scheduled for the near future (Creamer, 2020).

Within the hospitality industry, businesses are highly dependent on supply chain networks. COVID-19 breaks these supply chains themselves by a contagion effect. As one business collapses, the supplier above and the consumer below are almost certainly disrupted into a sinking whirlpool (Baldwin & Mauro, 2020). These disruptions rapidly breakdown business resilience and culminate in mass layoffs, inability to sustain financial commitments, risk of bankruptcy, and the ultimate closure for many (Bartik, Bertrand, Cullen, Glaeser, Luca, & Stanton, 2020).

Globally, businesses experienced incredible levels of disruptions. Most businesses are searching for ways to survive the COVID-19 pandemic. This is particularly true for business owners of SMEs who are left with little choice. Such businesses are finding ways of identifying their position amidst their employees, their customers and the legislation. Business owners have to juggle survival in the short-term, as well as long-term, as workforces and communities try to function and perform, while struggling to cope with what is happening in their daily lives (Accenture, 2020).

Following such reports, the author embarked on a research to study what and how businesses perceived the pandemic as seen from their point of view with particular focus on the hospitality and tourism industries.

3. Methodology

3.1. Research Design

The purpose of this research was to foster an understanding of how a particular social group experienced the world. This was accomplished through an explanation by the researcher about an event within the specific social context (i.e. business owners affected by COVID-19 pandemic). This explanation is for others (readers) to visualize how an area of the social world functions with many individuals each with a subjective worldview. The objective then is to collate a collective view of the event. Thus, the process is one of decoding information in which meaning is derived from the specific social context (Newman, 2014).

In this study, the axiological stand is that the researcher's value affects the conduction or outcome of the research studied. Simultaneously, the subject's values also affect the conduction and outcome of the research. By way of epistemology, the researcher's presence affects the outcome of the research by interaction with the subject. Ontologically, true knowledge cannot be obtained by repeated investigations because they may not converge on the same outcome. Truth therefore, is a social construction of those in a particular society. In this case, the society that was affected by the COVID-19 pandemic. The best research paradigm is therefore an interpretivist with a phenomenological approach (Creswell, 2014). Hence the research methodology needs to be conducted by an inductive approach through unstructured interviews or observation. The outcome of the research can change in time and results are influenced by both researcher and subject who co-create the conduction and outcomes of the inquiry process. This approach is commonly used in the social sciences and regarded as an analytic adaptation that represents a faithful vocalization of the people who experienced the phenomenon (Fendt, Wilson, Jenkins, Dimmock, & Weeks, 2014). A similar study using phenomenology on the COVID-19 outbreak has been conducted on perceptions and psychosocial consideration of Spanish nursing students (Collado-Boira, Ruiz-Palomino, Salas-Media, Folch-Ayora, Muriach, & Baliño, 2020).

3.2. Sampling Plan

The sampling size for phenomenological studies is recommended to be 5 – 25 (Creswell, 2014). This indicative sample size is helpful to note that ultimately, the required number of participants depended on reaching saturation of the quotation-coding process and no new theme, category, or information emerged from further interviews (Bradley, Curry, & Devers, 2007). Participant selection was by purposeful sampling and snowballing which helped to identify a total of 25 participants.

Trustworthiness of the research was attained by individual participants willing to describe their experience of the phenomenon. The individual participants agreed that they voluntarily express their true feelings and describe any relevant physiological or psychological experiences that occurred with the feelings. In all cases, data was

collected through in-depth dialogue between the researcher and participant. In phenomenology, this is also the point when analysis began. During the interview, the researcher simultaneously assessed if further data collection was necessary (Smith, 2010).

3.3. Study Participants
The study participants comprised of 2 coffee shop owners, 6 hotel owners, 10 restaurants and 7 tourist operators. The participants were aged between 35 and 62 years. There were 19 males and 6 females. All 25 participants owned their businesses and were directly affected by COVID-19.

3.4. Trustworthiness
Credibility is the equivalent of internal validity in quantitative research and is related to the trustworthiness of the research findings. Credibility is an indication of how well the research findings represent the acceptability of information extracted from the participant and the correctness of the extraction as perceived by the participant (Korstjens & Moser, 2018). Another aspect of trustworthiness is reflexivity. Here, the researcher must be aware of self-biases in the process of collecting, analyzing and interpreting data, and pre-conceived assumptions that may be inadvertently brought into the research. Thus, a researcher must put aside the researchers own biases so that the true experiences of respondents are reflected in the analysis and reporting of research (Korstjens & Moser, 2018).

3.5. Data Collection
The participants are mainly from hospitality and tourism industry. These include Coffee Shops, Hotels, Restaurants, Travel and Tour Operators. Data collection was primarily through telephone interviews with participants (business owners) who were affected by COVID-19. Using only simple unassuming guiding questions participants were asked to express their views of the impact of the pandemic. The guiding questions were unstructured and the expected response was a narrative of the participant's reflection. As interviews were made through the telephone verbal responses were noted impromptu. These were then transcribed to convert the spoken word to the written word to facilitate analysis immediately after the interview (Sutton & Austin, 2015).
Once all the research interviews had been transcribed and checked, pertinent quotations were noted and coded. Field notes compiled during an interview were useful complementary source of information to facilitate this process as the gap in time between an interview, transcribing and coding can result in memory bias regarding nonverbal or environmental context issues that may affect interpretation of data.

3.6. Data Analysis
The participant transcripts were read and re-read to look for communal views among the participants. The researcher implemented a process of bracketing by an iterative reflexive consideration of the quotations. Although total bracketing is not achievable the researcher made conscious attempts to put aside personal assumptions so that the true experiences of participants were reflected in the analysis and reporting of the research. Using this method, a total of 385 Quotations were made from the data analysis. These quotations were assigned to 34 Codes created directly from recurring views of the participants. No Code was predetermined. Coding and data analysis were done using Atlas.ti (Atlas.ti, 2020). The conceptual framework of this research is shown in Fig.1.

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810
Fig. 1. Conceptual framework of phenomenology research in this study.
Fig. 2. Codes and quotations from participants.

From this data, the 34 codes (Fig.2) were assigned to meaningful concepts pertinent to the objectives of the research questions. A total of nine concepts were identified as shown in Fig.3. These were further grouped into three categories comprising Individual (staff and social distancing), Business (supply chain, business, resurging, cash flow and work remotely) and government (initiative and recovery plan).

Category	Cum. Code	Concept	Code	Code Density
Individuals	157	Staff	71	
		Social Distancing	86	
Business	167	Supply Chain	33	
		Business Relations	85	
		Resurging	16	
		Cash Flow	6	
		Work Remotely	27	
Government	61	Initative	46	
		Recovery Plan	15	

Fig. 3. Code density, concepts and categories.

Of course, there were many ways of synthesizing and presenting the data. However, any conclusions drawn by the researcher has to be supported by direct quotations from the participants. Thus, it will be clear to the reader that the themes that emerged in the study are solely from the participants information and not from the researcher (Creswell, 2014).

4. Thematic Analysis

From considerations in the last section, three themes that emerged purely from the quotations assigned to codes, codes assigned to concepts and concepts assigned to categories. Themes are generalized propositions emerging from a particular clade of categories, concepts, codes and quotations. Themes can also include the relationship of codes, which tag data that link concepts and categories to each other (Bradley, Curry, & Devers, 2007). In this study, three themes emerged as identified by Individual, Business and Government as shown in Fig.4. The thematic analysis is explained next. Note that the thematic concepts comprise of codes given as the heading for each paragraph.
Fig. 4. Emergent themes for Kuwait hospitality and tourism industry.

4.1. Theme Individuals

The emergent theme of concepts and codes for Individual is shown in Fig. 5. A detailed explanation of each code follows.
Fig. 5. Theme of concept and codes for individual.

4.1.1. Staff

Public Assistance: Managers expected public assistance from all stakeholders including customers, staff and the public.

Reduced Staff: Many businesses had to cut their staff by half. As branches were shut down the workforce had to be reduced between 20-50% with the business disruption. The staff reduction was necessary to overcome the situation. Only key staff were employed. This was also a huge challenge as some employees were already on vacation or planning to do so. The shortfall in cash revenue also meant the salaries had to be cut. Some employees planned to leave as there is no work and salary reduction was not viable. Availability of new staffs for business also met with challenges aggravated by the lockdown and curfew.

Staff Morale: Staff morale was greatly affected as staff experienced a high level of mental strain and frustrations as they faced this situation for the first time. Salary cuts to the skilled staff greatly affected their morale. Employees whose vacations were approved had to be cancelled resulting in lost confidence and poor mental attitude. Work hours were reduced so employees were not over-worked for the reduced salary. Training and counselling were conducted to boost the employee morale. Additionally, a savings fund was suggested for employee welfare.

Workforce Re-planning: Business managers were mainly concerned with the employment of workers as most had lost their employment with them. Hotels had to continue to support customers already with them. Only essential services like housekeeping could be provided as many employees were asked to go on leave. A core employee group was maintained to service elite customers. Three shifts were reduced to two. Reduced workforce meant that workload had to be distributed. In the travel industry, work was conducted within the curfew hours. Some staff were asked to work from home much like call centers.

Health Examination: Coffee shop managers ensured that health examinations were conducted by encouraging their staff and customers to make use of proper PPEs while entering their premises. Orders were mainly through phone and custom-made mobile app specially designed for this purpose. Hotels kept track of their staff who worked from home on a regular basis. Any employee tested positive was transferred to quarantine for medical treatment. Restaurants and travel industry planned installing thermal scanners on premises to fight the pandemic. Routine medical examination was conducted for staff. Businesses promoted a hygienic and sterile environment for employees and customers.

4.1.2. Social Distancing

Stay Home: Social distancing was very important. Coffee shops urged their staff to stay at home until the situation improved. Although most hotel staff stayed in the accommodation provided, they were told to stay at home. Since many of them stayed in lockdown areas this made their transportation difficult during the curfew times. In the travel industry, around 60-75% of the staff had to stay home. Among them 50% worked from home.

Stay Safe: Most coffee shop customers who had their morning coffee stopped coming in fear of the virus spread. So, coffee shop staff were directed to practise social distancing. Menu cards contained important contact numbers of health centres for contact during an emergency. Hotels directed their staff and customers to practice social distancing at all times. Transportation arrangement was available to help customers reach their destination between curfew times. More safety procedures were planned for implementation to ensure customers were safe and healthy. Restaurants staff always maintained social distancing. This constrained in employing few staff in the kitchen area with strict rules to practice social distancing. In the travel industry, organizations created an elite

group to monitor the safety measures used while transporting customers to the airport. Rules and principles were set for employees to follow in order to create a safe working environment.

Personal Protection Equipment: Coffee shops had to provide personal protective equipment (PPE) to staff. Customers were provided with essential services like food and PPE. The PPE increased the monthly expenses. Additionally, masks and a pair of gloves were provided to customers who ordered above a minimum amount. Hotels also followed safety precautions with the use of PPE like masks and gloves. Providing PPE to staff and customers increased expenses for the company. Restaurants also provided PPEs to staff and customers. Strict measures were taken to promote the use of personal protective equipment in the business premises. Essential services like food, water, gloves, sanitizers and other PPEs were made readily available. In the travel industry, PPE was made available to staff and they were encouraged to use it when they travelled or had contact with the customers as recommended by the health authorities. Customers were encouraged to use PPEs when they entered the premises.

Lockdown: All businesses were restricted to function during the lockdown. As the government shut down majority of the businesses, other related businesses had to shut down. Many branches closed due to the lockdown as part of government decisions. Many staff who could not travel to work worked from home.

Safety Measures: Safety measures seem to be the most concerning aspect. Staff were provided with gloves and masks to protect themselves. All measures were taken to ensure staff and customers were not infected. PPE was used without wastage. Suppliers who followed precautionary measures and safety policies were preferred. Staff were given specific directions on hygiene measures to follow as recommended by the government. As an organization, many have implemented the 5-meter apart policy even though this meant reducing the number of customers in the shop. In the coffee shops, tables were sanitized before and after customer usage. Hotels provided sanitizers in the hall way and in front of lifts for both staff and customer safety. Timely brochures containing latest safety rules published by the government were distributed among the staffs and resident customers to make them aware that all were together in the fight against the pandemic. This strategy helped the customers to identify the business as taking safety as the first priority. Hotels undertook to provide accurate information so clients were informed about the virus and steps taken to fight it. Rooms were disinfected before and after a client's stay. Sanitizers were installed in the premises. Social distancing was made mandatory. Safe travel and other precautionary measures helped the customer confidence. In the travel industry, premises and branches outlets were sanitized every alternate day to ensure safety. Safety policies were implemented for the safety of the employees and the customers who entered the premises for their travelling needs. Only safe travelling destinations were included in the packages so that customers travelled without fear of the virus.

4.2. Theme Business
The emergent theme of concepts and codes for Business is shown in Fig. 6. A detailed explanation of each code follows.
Fig. 6. Theme of concept and codes for business

4.2.1. Supplier Chain

Disrupted Supply Chain: Businesses stopped and the supply chain was difficult to maintain. Suppliers were also in the same situation unable to provide their services. Hotels faced severe challenges of supply chain management since food suppliers and restaurant caterers had stopped working during the lockdown and curfew times. Restaurants faced similar problems since it was difficult to maintain relationship with vendors and suppliers who reduce their services to a minimal level.

Movement Control: The movement control greatly reduced customers visiting coffee shops and the sales went down. As public gathering stopped, only door delivery was provided. This meant acquiring passes for transporting employees to work during curfew conditions.

Disrupted Production: Suppliers had passes which made the availability of essential supplies. The orders for food supplies were reduced as there were few customers. Hotels and restaurants reduced the food items to sustain business. In the travel industry, transport providers, accommodation providers and tour operating service providers were shut down as it was difficult to coordinate tour packages and arranging accommodation for tourist customers.

Participative Suppliers: Some more participative suppliers generated plans and ways of continuing working relations. Manufacturers and food suppliers were contacted directly particularly those who could arrange to transport the supplies. Transportation cost was borne by the business so as to maintain a good relationship with the suppliers. Travel passes were also arranged by the business with cooperative suppliers. Restaurants made

agreements with leading pharmacies and other outlets to provide personal protective equipment like gloves and masks. In the travel industry, customer relations were maintained through emails and other social media.

4.2.2. Business Relations

Reduced Revenue: Reduced revenue was seen across all businesses. Coffee shop revenue was affected through direct sales. People refrained from door deliveries particularly during total lockdown. For hotels, many bookings were cancelled and the money refunded to customers. The government also required that hotels were shut down resulting in huge losses. Revenues dropped to 30-50% during the lockdown. Restaurants were affected by loss of takeout and delivery which had stopped. Customers driving in for food and home deliveries had stopped. The cash flow had come to a standstill. Phone orders which generated 40% of the revenue stopped. Private catering and bulk private orders stopped. In the travel industry, around 60% of customers were refunded fully as they had booked before the shutdown. Another 40% had to be provide partial refund as they booked tickets more than 4 months before the shutdown. Travel packages also decreased as customers who booked them backed off. The reduced work hours further affected productivity.

Borrow Money: Hotels could not borrow money from the banks as the banks were shut down and loans were not readily available. Travel agents also faced similar problems as they could not opt for loans to hold back losses as the banks shut down their activities.

Reduced Business: Coffee shops were partially open during non-curfew periods. Nevertheless, business was affected from the beginning of the virus outbreak. For hotels, customers who intended to stay cancelled their reservations. The occupancy rate declined considerably. The cash flow was affected as the credit booking system stopped. Food prices were reduced in the restaurants. All these seriously affected the hotel business. Restaurants had to operate in a regulated timeframe especially the non-curfew hours, but adhering to the restricted time periods was very difficult. In the travel industry, accommodation providers for tourists were all shut down. As the government introduced further restrictions, travel agents had to follow the shut down operations completely. The closure of the airport posed a serious blow which further affected the business.

Redesign Market Strategy: Coffee shops introduced more discounts and complements for their customers. Participative suppliers would be considered first after the lockdown. Brochures with safety measures for the pandemic would be designed and printed for customers. Hotels were keen to adopt cloud-based Property Management Technologies which enable activities of the hotel from a remote distance. At the same time, customers would be encouraged to use custom-made mobile application that served the customers without being present at the hotel. Hotels also devised plans to include more discounted rates for routine customers. This provided personalized offers to customers to fulfill the needs of customers. This new policy would promote an emotional connection between the hotel and the customers. Restaurants aimed to provide good nutritious food to their customers by implementing new recipes in their menu. Food will be cooked on order and supplied fresh. Restaurants chose the internet as their business platform. In the travel industry, new strategies would be created to attract customers and stakeholders. Customer care cells were planned to cater customer queries.

Mounting Operating Costs: Businesses had to pay salaries to employees and take care of their safety resulting in increased financial expenses. For restaurants, it was a difficult task to pay staff during the lockdown and curfew. The unavailability of funds led to inability to pay staff salary timely. For travel agents, refunding money demanded by customers incurred severe operating losses.

Loss of Business: Coffee shops were disrupted of daily routines. Loss of business was very high during lockdown. With the ban of public gathering customers stopped regular order of coffee. Most of the revenue generating branches affected by the lockdown closed business within the first two weeks of the pandemic. Closing down the coffee shop resulted in huge losses. For hotels, the pandemic plunged the industry tied to most other businesses locally and globally. The high level of cancellations and postponements in bookings caused severe loss of business. The hotel business had been affected drastically. For restaurants, the government closed all food outlets during the total lockdown resulting in total loss of business. Many branches in the lockdown areas were also shut down completely. The closure of local markets resulted in loss of business. With the lockdown, the travel industry came to a standstill. Many pre-booked travels were cancelled. People postponed their travel dates. Vacation packages were lost. The airport was shut down. And, much money had to be refunded resulting in tremendous loss of business.

4.2.3. Resurging

New Policies: The hotels conducted research as how to manage the hotel without direct contact with customers. They worked on their management policies regarding room service, advertising and introduced a proper check-in and check-out process. One of the main policies was to generate feasible rates and discounts to customers. Another was to attract millennial travellers. The new policies and strategies would be implemented in their business. Restaurants generated new policies and regulations for employees to follow. The travel industry had introduced a new policy of including in their brochures and pamphlets, information about the virus and also locations of health centres to contact.

Social Media: Hotels were keen to conduct sales, advertising and business development activities remotely. A hotel app would be used to entertain their guests without actually being present there. Hotels also devised plans to retain existing regular customers by giving them latest updates of the situations through a portal. Restaurants would use social platforms to provide the latest updates on the policies of the government to their employees. In particular, employees would be informed of new developments regarding rules and regulations by the government through WhatsApp Group Messages. The system will also be used to take orders through WhatsApp numbers. A WhatsApp Group was created for employees at all branches. The employees were encouraged to communicate through the Group for any concerns. The daily menu was also be available through WhatsApp.

Organizational Transformation: Hotels ensured that different departments functioned together with management to produce a safe working environment to customers.

Quarantine Facility: Hotels were forced to provide premises for quarantine purposes. Thus, the flow of customers was stopped. Another hotel, had given its premises and transport facilities to transport nationals brought back from other countries to the quarantine areas.

4.2.4. Cash Flow

Increasing Operating Costs: The travel industry incurred high expenses to provide for staff welfare. Premises had to be frequently sanitized to enable a safe environment even though this was costly. Having to refund money completely for many travel bookings affected profits and commissions were lost from business partners abroad for arranging stays for customers.

Increased Financial Burden: Restaurants could not have private borrowings as the banks and other financial institutions were closed. Refunds had to be given to the customers who cancelled their bookings. Inevitable, employees had to bear salary cuts.

4.2.5. Work Remotely

Digital Solutions: Working from home is not an option for coffee shops. However, customers could order food and drinks through a mobile app rather than over the counter. This enabled customers to pre-order and pay through the app. The customers benefitted by pre-ordering, table booking, and paying for beverages beforehand. This made their coffee available once they arrived. Of course, different options like selection of number people, different flavours of coffee and preferred table was available in the App. In the hotel industry, digital solutions would enable remote business control. During the lockdown, most managers and supervisors worked from home. This is the future trend to implement measures to track activities remotely. It is likely that future business will be mainly based on technologies. As most of the businesses around the world are switching to embrace technology in their business, it is high time that hotels implemented the same. Introduction of Property Management Technologies was the future strategy to sustain. Contactless method of engaging guests would be a new strategy introduced in the hotel business. Therefore, it was appropriate to embrace technology in business. Many explored how to implement this as restaurants turned to technology. Some introduced a Facebook page to provide customers with new updates and nutritious recipes. Hotels planned to develop software through which customers could order directly. Customer requests would be forwarded to computerised system. The travel industry devised plans to give discounted rates and safe travels to the customers who booked through technology apps.

Online Presence: Many hotel supervisors and managers had been working from home. A majority of team leaders were asked to work from home to understand customer queries. An online presence would implement technologies to serve customers without coming into contact with them. Staff could work from home to act as a customer care cells that answered customer queries. Online campaigns were promoted to protect staff and customers.

4.3. Theme Government

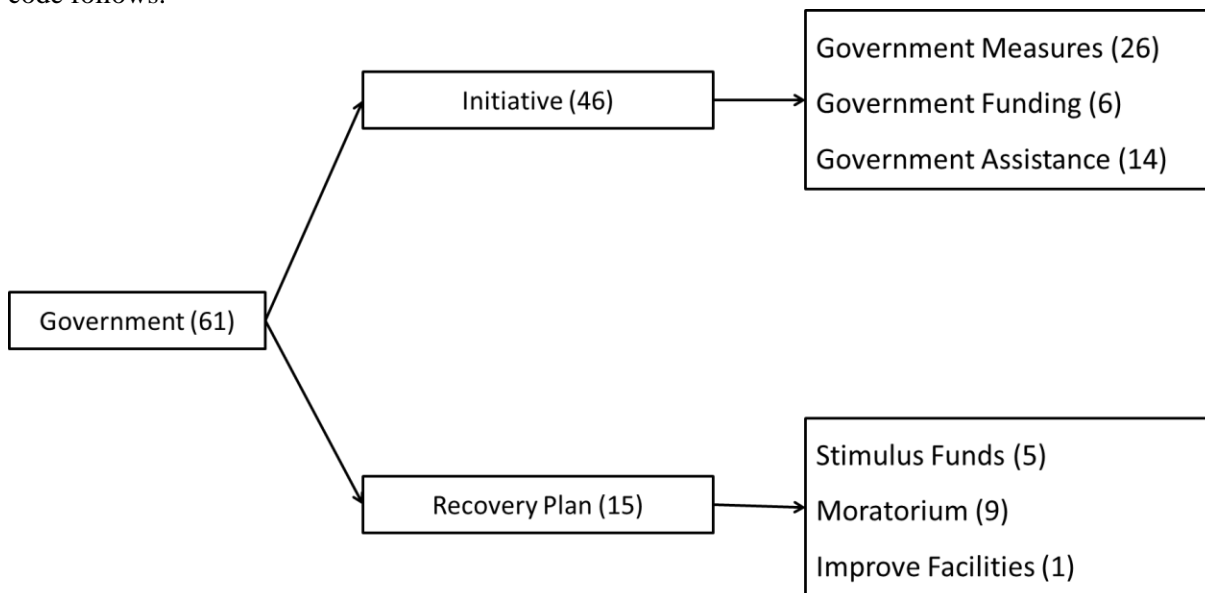
The emergent theme of concepts and codes for Government is shown in Fig. 7. A detailed explanation of each code follows.


Fig. 7. Theme of concept and codes for government.

Make your research more visible, join the Twitter account of ENTREPRENEURSHIP AND SUSTAINABILITY ISSUES: @Entrepr69728810

4.3.1. Initiative

Government Measures: In order to recover from the pandemic, a limited and steady operation would be most suitable with the government health authorities' approval. Coffee shops anticipate that there will be more supportive measures from the government and banks. While vaccines and medicines are developed businesses will adopt to live with the virus. Safety measures need to be improved in in admitting people to coffee shops. Sanitizers will be installed at occupied tables to enable customers to use then when needed. Banks are expected to extend their loan waivers so that money was available for re-investing in the business. As the government introduced 5 phases of reopening, hopes are that coffee shop business will function normally in the future. Hotels have followed the government's instructions step-by-step. As the government is considerate in supporting the hotel and hospitality industry, it is hoped that the government will continue to support the hotel industry. If the government advocates living with the pandemic, hotels would strictly follow the relief methods by the government. It is also expected that the public will support by complying with safety precautions as explained by the government. Hotels intend to work side by side with the government's efforts to fight the pandemic along with other NGOs. Restaurants plan to recover from the pandemic by practice business according to the government guidelines. In case the government advocates living with the pandemic, restaurants will follow the government guidelines and be socially responsible. Hotels will need to adapt to the new situations; with the government support of granting permission to the restaurants to function. In the travel industry, if the government advocated living with the pandemic, the industry will operate along with the government's guidelines in the best interest of the businesses. Moreover, the banks announced waiver of interests and loans helped businesses to save money for other expenses. Following government instructions would be the best way to mitigate the pandemic by taking measures and steps to control the spread of the virus.

Government Funding: Coffee shops expect the government to introduce more measures to help the business. For hotels, the various subsidies and moratorium announced by the banks and government helped to ease the financial burden to a large extend. For restaurants, the availability of government fund would be utilized for generating an employee welfare fund through emergency assistance. The government sectors are expected to set aside further funds for sustaining the restaurant business sector. The travel industry also expects the government and the banking institutions to introduce more grants and funds to help business growth.

Government Assistance: Coffee shops anticipate government support by providing operation facilities after businesses reopen after the lockdown. Hotels anticipate the public and the government will assist the implementation of new technologies in their venture. Furthermore, an increase in the lending period will also help in loan repayment. This assistance could also be expected as a cooperation not only from government but also private, public and semi-government sectors. This will help hotels stay up-to-date with the latest government policies introduced and relief measures introduced for recovering from the pandemic. However, it is expected that the government continue to introduce new plans and policies to help the restaurant businesses. Since, the restaurant business is a booming business, special policies should be generated by the government to support growth. The travel industry also expects further relief from the waiver of loans and interests by the banking institutions. This would help recover the loss incurred due to refunds and cancellations. The industry believes that the government will announce more incentives to the travel industry. The government of Kuwait is considerate in their efforts to bring the economy back to normal.

4.3.2. Recovery Plan

Stimulus Funds: Hotels suggest stimulus funds offered by Kuwait Banking Association and Central Bank of Kuwait will help to ease the loss incurred during the pandemic. Loan waivers by the financial institutions will also help them to pool the money for further developmental programs after the pandemic. Thus, it is expected that the

government will support by introducing more stimulus funds to support SMEs like the hotels. Restaurants suggested that stimulus funds like reduction in the discount rates and increase of limit of finance to a 100% had proven to accumulate the money for necessary changes. The stimulus package announced by various banks had also benefited them.

Moratorium: The government's 6-month moratorium helped coffee shops to sustain during the lockdown. Even though, they were functioning between the curfew periods and there was enough revenue generated, the moratorium helped greatly. For hotels, the 6-month moratorium helped to pay important necessities like providing salaries and buying PPEs for employees and resident customers. The 6-month moratorium by the government helped the hotels to recoup the losses and invest the money back into business. For restaurants, the tax reliefs and 6-month moratorium helped them to utilize the money to pay staffs. It lowered the risk of SMEs by about 25-75%, thus helping businesses to sustain. The moratorium also helped them to sustain through pandemic. It also helped them to provide PPEs to employees. Restaurant admitted that loan waivers and moratorium introduced by the government had greatly helped them sustain during the difficult situation. The 6-month waiver of loan repayments proved to be helpful. In the travel industry, the moratorium announced by the government helped to survive the losses incurred due to the virus. The moratorium helped to ease the loss suffered during this period particularly in employee retention as they were paid salaries and bonuses for Ramadan.

Improve Facilities: The hotel took the pandemic period in a positive way by using the period for renovation and maintenance.

5. Discussion

Based on the findings described in Section 4, the following questions are answered.
1. How are individual business owners affected by the pandemic?
2. What are the main issues and their resolutions to bounce back by companies?
3. What government assistance do business owners expect in bouncing of the pandemic?
4.

5.1. How are individual business owners affected by the pandemic?
There are two ways in which business owners are affected.
First, business owners are severely affected by staff issues. Many SMEs had reduced their staff to between 20-50% with disrupted business. This reduction in staff manning the business was due to the inability of the SME to continue to hire the employees. Only key staff were employed due to shortfall in cash revenue. Staff morale was highly affected due to the loss of confidence associated with facing the problem first time together with the salary cuts. Business managers were mainly concerned with the employment of workers as most had lost their employment with them. Reduced workforce also meant that workload had to be distributed among remaining staff. Health examinations, thermal scanners and the usage of PPEs was necessary to promote a hygienic and sterile environment for employees and customers.

Second, many of the staff were asked to stay home for safety reasons. To ensure customer safety, staff were directed to practice social distancing. This was very constraining in businesses like coffee shops, and restaurants. Not only businesses had to provide essential services to their customers, they also had to provide Personal Protection Equipment including masks, gloves and sanitizers to customers entering the business premise. The effect of the lockdown was that, as more businesses shut down, many other inter-dependent businesses had to follow. Safety measures seem to be the most concerning aspect. Staff were given specific directions on hygiene

measures to follow as recommended by the government. Many had implemented the 5-meter apart policy even though this meant reducing the number of customers in the premises.

5.2. What are the main issues and their resolutions to bounce back by businesses?

The main issues faced by businesses was business relations and supply chain disruption. Business relations was the predominant factor. Many businesses were affected by reduced revenue. Revenues dropped to 30-50% during the lockdown. The cash flow had come to a halt. Phone orders which often generated 40% of the revenue also stopped. Around 60% of customer orders had to be refunded full payments as their services could not be fulfilled. The reduced work hours further affected productivity. Loss of business also accompanied the ban of public gathering customers. The closure of local markets also resulted in loss of business.

The supply chain was the next most important factor. As businesses closed, the supply chain was difficult to maintain. Other suppliers were similarly affected and unable to provide their services. Coordination between suppliers was difficult. Nevertheless, some suppliers were more participative by generating plans and ways of continuing working relations. For those who could arrange to transport the supplies, the transportation cost was borne by the buyer business so as to maintain good relationship with the suppliers. This would help broken supply chain links to be reconnected and enable service flow. Suppliers reconnected after the pandemic are likely to have a mutual business-survivor bonding that will quickly thrust business recovery.

The resolutions to rebound the business was clearly in place. One way to bounce back diminishing business was to redesign market strategy. Businesses introduced more discounts and complements for their customers. New strategies to include brochures with safety measures to follow during the pandemic was designed and printed in customer brochures.

A second way to rebound the business was to use social media platforms and portals to provide the latest updates on government policies along with business applications. In particular, employees would be informed of new developments through WhatsApp Group Messages. The system would also be used to conduct business through WhatsApp groups created for employees.

A third way to rebound the business was to develop new market strategies to work remotely with online presence and digital solutions. Customers were encouraged to use custom-made mobile application that helped to serve customers. Some business used cloud-based technologies to enable remote service activities. The method also provided personalized offers to customers and helped to fulfill the customer needs as much as possible. The new market strategies promoted an emotional connection between the business and the customers.

5.3. What government assistance do business owners expect in bouncing of the pandemic?

There are two facets to what government assistance are expected by businesses. These are government initiatives and government recovery plans.

The government initiatives expected are clearly on government measures to enable a steady operation with the approval of government health authorities. Businesses anticipate more supportive measures from the government and banks.

Many businesses also expect more government funding through grants and subsidies to be announced by the government to ease the financial burden to a large extend. The availability of government funding would be

utilized for employee welfare through emergency assistance. Moreover, the banks through the government are expected to announce waivers of interests and loans to further helped businesses to cover expenses.

Businesses anticipate the government assistance through incentives to implement new technologies ventures. This could be done by an increase in the lending period to help businesses to relax loan repayment. This assistance could be expected as a cooperation not only from government, but also semi-government, private and public sectors.

As for recovery plans, businesses expect the government to introduce stimulus funds. Stimulus funds would be used to ease the loss incurred during the pandemic. Loan waivers by the financial institutions will help businesses pool money for post-pandemic development programs. Business suggested that stimulus funds could be based on an increase of finance limit to 100% of value to accumulate money for necessary changes.

All businesses agreed that government recovery plans such as the 6-month moratorium helped them to sustain during the lockdown. The moratorium helped to pay necessities like providing salaries and buying PPEs for employees and customers. The moratorium also helped to recoup losses and invest the money back in to business.

5.4. Implications of the Findings for Practice
The research showed three themes identified in the research. Firstly, a fairly extensive outline of the effect of COVID-19 on SMEs has been elucidated. Secondly, the extent of problems faced by SMEs has been visualized from the view point of the business owners. Thirdly, and most importantly, the research has exposed in-depth expectations of SMEs as to how governments need to provide various initiatives and recovery plans to bring back business to pre-COVID-19 levels. Specific initiatives include government measures to revive hospitality and tourism industries with government funding and stimulus funds.

5.5. Recommendations for Further Research
Recommendations for further research are:
1. Conduct similar research on specifically how existing businesses struggling to sustain themselves could be assisted to regain their pre-COVID-19 levels of business. This could in fact be conducted at a national level. Although government bodies may have their perceptions of what needs to be done, the real needs of the business are best elucidated by a suitable phenomenological study. Such a method would have a better chance of identify true business needs.
2. Another study could be done on business owners who have lost their business. Bearing in mind such failed businesses failed for reasons beyond their control, it would be prudent to identify more accurately, how the failure occurred and what actions can be taken to revive these businesses. This would be best done by government bodies that administer to the local SME businesses.
3. Research of SME financial predicaments by banks and financial institutions is another important aspect. Banks and financial institutions stand to gain most by understanding the plight of failing and failed businesses and, creating a variety of business products (i.e. waivers, reduced interest rates, loans, funds and incentives) to support failing businesses and revive failed businesses.

5.6. Limitations

The limitations of the study are bound to the qualitative nature of the study although much effort had been included to reduce the subjectivity of the data. Researcher bias though reduced by bracketing cannot be completely avoided since some bias is not intrinsically knowable to the researcher.

Although the sample size was fairly large, and the interviews were conducted to saturation of quotations and codes, it would be difficult to assume that the selected participants were representative of the larger population.

6. Conclusion

This research has espoused phenomenology as a remarkable way of understanding social perception of a society from their own point of view. This phenomenological study exposed three themes of the COVID-19 pandemic on the collapse of SMEs and failing employment. The first theme revealed the plight of SME business owners and the hardships faced due to the pandemic. The second theme uncovered extensive experiential predicaments of the businesses. The third and most important theme revealed quite clearly, what SME business owners expect of government and financial bodies to support surviving businesses and revive failed businesses.

Abstract. Currently the "green" economy is an important part of positioning in the international arena as an environmental component of sustainable development. Russia, as an active party in the international arena, supports resolutions on the "green" economy development and "green" financing tools for resolving issues of climate-resistant economic growth. Factors and trends in the Russian "green" economy development are radically different from most developed countries. At the same time, Russia has undeniable advantages in terms of preserving natural landscapes and the ecosystem services' potential. Russia also has huge and almost unused opportunities for "green" growth. Our article is devoted to these problematic economic issues related to the "green" investment development. It is a basis for environmentally sustainable evolution. We discuss the latest trends and facts in the the"green" economy development of Russia. In addition, we describe possible promising directions for its growth in the future. Our results can be interesting and useful for researchers and experts working in the field of strategic management, spatial development and innovation economics. It is attractive for stakeholders and politicians involved in the economics and environment issues.

Keywords: "green" economy; "green" investment; "green" growth; sustainable development; social responsibility; low-carbon development

1. Introduction

According to the Resolution adopted in 2012 by the UNO General Assembly, economic development leads to rapid accumulation of physical and human capital today. It is carried out at the expense into excessive depletion, degradation of natural capital and increasing inequality between people (The future we want, UN, 2012). Most of the world's countries agree with this aspect at the global level. Particularly in 2016-2017, 132 countries proposed a number of initiatives at the state level in the " green " economy developing area. These countries account 82% of all harmful emissions. As a result, the states that did not participate in the development of rules and standards in the "green" financing area need to accept the conditions and rules for the "green" economic model's development functioning today. These conditions and rules were developed by more active countries (Ministry of Finance of the Russian Federation 2017). As a result of the Paris agreement on climate change, all countries, including Russia, are required to have long-term low-carbon development strategies and plans for climate change adaptation and to implement appropriate measures. At the same time, the Paris agreement assumes the voluntary contribution principle for each country to the solution of the global problem into climate change (Principles of sustainable development, VEB RF 2016).

Taking into account Russia's membership in the UNO, it should be noted that the country's movement towards sustainable development requires a close study of foreign practice in forming a "green" economy model by the adaptive approaches. It is important to keep in mind that sustainable development is such form of development that is socially responsible, economically realistic and environmentally friendly (Tarkhanova, 2018). According to R. Perelet "the search for a new development model has led to the evolution of the sustainable development paradigm, the concept emergence of a "green" (ecological) economy and a deeper understanding that the economy and society should fit into natural systems and their limitations but not vice versa" (Perelet, 2011). Of course, the green economy is not a separate segment of the economy but it is its new adequate appearance (Dvoretskaya, 2017).

2. Literature review

Comparing the use of green economy in politics with conceptual approaches, it should be noted that the concept of green economy in the academic world has a long history. According to Loiseau, Saikku, Antikainen and others, "green economy" – term was firstly introduced by Pearce D. in 1989. This British researcher and his co-authors introduced it in response to the underestimation of environmental and social costs in the current price system (Loiseau et al., 2016). In particular, Pearce D. concluded that the "green" economy is the middle way to achieve sustainable development between the rejection of any economic growth or activity limitation and unrestricted free markets (Pearce, 1992). The expansion of the "green" economy concept has started and continues today due to British experts (Pearce, 1992; Barbier, 1987) in the field of environmental economics.

In fact, there is no generally accepted definition of a "green" economy. This is a rather controversial term that can be defined from various points of view, based on options for strategies depending on interests and worldview (Pattberg & Zelli, 2015; Mazzoni, 2020). Experts of the United Nations environmental protection organization (UNEP) have a fairly broad view of the green economy. They suggest define it as an economic activity that "increases the well-being of people and ensures social justice and significantly reduces risks to the environment (Towards a "green" economy, UNEP 2011). It is also the "green" economy definition in the Russian legal field in terms of sustainable development. If we consider this concept more narrowly, we can find that the "green"

economy includes some types and results of economic activity that contribute the life quality improving and living environment. It happenes with modernization and increasing production efficiency. According to Qingqing Weng, He Xu and Yijun Ji, all available definitions show that a "green" economy is an "umbrella" concept. It includes various consequences for growth and well-being or reducing efficiency and risks with natural resources using (Weng et al., 2018).

Today the "green" economy concept is positively perceived by Russian science. There is a variety of publications into this area in recent years (Lipina et al., 2017; Zhitovskaya, 2016; Chernomorova, 2016; Pchelincev, 2016). However, despite the large number of scientific publications devoted to the "green" economy, the problem of forming the "green" economic growth's model in Russia is studied insufficiently.

The importance of "green" growth is often discussed at the state level in Russia. According to the approved "Fundamentals of the state policy in the Russian Federation environmental development field for the period up to 2030", the strategic goal of the state policy in the environmental development field is to solve socio-economic problems. They ensure environmentally oriented economic growth.There is also a favorable environment preservation of biological diversity and natural resources.The claim to meet the needs of current and future generations, to realize the right of everyone to a favorable environment, strengthening the law in the environmental protection field and environmental safety are mantioned there (Fundamentals in state policy into the field of the Russian Federation environmental development for the period up to 2030). Moreover, the "green" theme has recently become an agenda for the Bank of Russia (Central Bank of the Russian Federation 2019). Global challenges related to climate change, accumulated environmental damage and reduced biodiversity are contributed to the creation and development of special institutions and financial instruments for sustainable development. They also include green bonds on foreign financial markets. It happens in accordance with the main development directions of the Russian financial market for the period 2019-2021. Russia can not stand by and must join the global process. This country must work out the national system's formation of financial instruments for sustainable development, the methodological and verification system's organization for responsible financing instruments.

This article discusses promising directions for the "green" economy development in Russia.It includs "green" investment issues and "green" growth assessment with the key indicators' using. We analyze the dynamics, the "green" investments' share and the structure of their funding sources. The study is based on an extensive amount of scientific literature. It allows us to make comparisons, provide relevant examples, extrapolate our ideas and results.

3. Materials and Methods

The methodology of the study was based on the methods of calculating the dynamics indicators characterizing the "green" economy data and data on "green" investment, as well as on a comparative analysis. In order to achieve the objectives, we used specific data from the Federal State Statistic Service in terms of green investment in accordance with the implementation of the investments' dynamics in fixed capital aimed at environmental protection and rational use of natural resources in 2000-2018. In order to analyze and assess the results of the green investment, we used the methods of comparing the calculated indicators of "green" growth of according to the Global Cleantech Innovation Index and data on the Global green economy index.

4. Results and Discussion

Adopting a new paradigm for social development implies a transition to a circular economy. The above requires the reduction of greenhouse gas emissions, the utilization of wastes, and the use ofrenewable energy sources (Bazaluk et al., 2020). The "green" economy does not only recognize and take into account the importance of natural capital. It also provides for investments into environmental protection in order to preserve and increase it.

Climate change is a serious threat to the planet. The implementation of the Paris agreement on climate change in 2016 make it possible to draw the attention for investors and businesses to the necessity, inevitability and acceleration of the international transition to a "green" economy. Presumably, the implementation of this agreement can speed up the technological innovations' introduction and appropriate policies that allow investing in "green" and low-carbon assets, projects (International Finance Corporation 2016).

Moreover, huge investments are needed to finance and support projects for the environmental protection.Among them there are less carbon-intensive technologies and infrastructure. The question is how to make buildings and entire cities more water-and energy-efficient, based on wind and solar power stations, low-carbon transport and technologies (Peeters, 2005; Štreimikienė et al., 2016; Moumen et al., 2019).

Morgan Stanley Capital International (MSCI) experts dealing with environmental, social and managerial aspects have developed special tools for investors (see Table 1). They can implement their responsible investment strategies, excluding assets with high greenhouse gas (GHG) emissions from their portfolio.

Table 1. Special tools for implementing a responsible investment strategy

MSCI ESG CARBONMETRICS	quantitative information on GHG emissions and carbon intensity, reserves and potential emissions by type of fossil fuel for more than 8,500 companies.
MSCI ESG CLEANTECH METRICS	defines the prospects for the development of "clean" technologies in five areas: alternative energy; energy efficiency; "green" construction; pollution prevention; water resources management by the sustainable development principles.
MSCI CARBON PORTFOLIO ANALYTICS	evaluates the "carbon track" and "carbon risks" for portfolio of assets with benchmarking.
CARBON FOOTPRINT CALCULATOR.	allows you to generate statistics on GHG emissions at the button's touch (built on the basis of Microsoft Excel).
MSCI GLOBAL LOW CARBON AND ENVIRONMENTAL INDEXES	indexes that allow comparisons on the level of environmental responsibility and GHG.

Source: compiled by the authors

Sustainable or responsible investment as an investment model appeared with the introduction of the sustainable development concept in 2012 (United Nations Conference on Sustainable Development 2012). The purpose of this investment is not only to generate income for the investor, but also to create positive social changes, reduce the negative impact on the natural environment with ethical standards (Ministry of Finance of the Russian Federation 2017).

It is significant that the practice of socially responsible investment in Russia has not yet received proper development. In particular, a national regulatory system and a strategy for setting standards on socially responsible investment are not established. At the same time, some Russian companies are already acting as participants in the responsible investment's field.

Regular measures' implementation aimed at nature protection and construction of treatment facilities are required to improve the environment and further reduce emissions of harmful substances into the atmosphere.These measures require huge investments in the " green " economy.

There are some priority sectors for "green" investment in the global aspect (see Fig. 1) in accordance with the concept of UNEP. This organisation promotes actively the "green" model formation of economic development. They are: forest sector (afforestation strife); agriculture (developing sustainable management); water resources sector (solving water supply problems and improving water consumption efficiency);" green "fishery (overcoming a sharp drop in fish stocks); energy sector (the transition to alternative energy sources and production, increase of its use efficiency); industrial production (eco-efficiency increasing); green transport (development of environmental and energy-efficient transport modes); eco-tourism (the "green " infrastructure development, new types of eco-tourism, maintenance of biodiversity); "green" construction (construction of new "green "   buildings and existing buildings' renovation).
Fig. 1. Priority sectors of "green " investment
Source: compiled by the authors

In our opinion, the alternative energy is the foundation of "green" growth in Russia among the represented sectors. It is due to:
- firstly, the importance of the energy sector in the economy. It plays a fundamental role into the economic development and national security of the country. The alternative energy sources development is promising and highly perspective. It is despite the fact that the territories and subsoil of

Russia are quite rich in energy resources. This trend is very characteristic and significant for the Federal regions that use imported fuel;

- secondly, the increasing trend of depletion into the most affordable and profitable reserves of classical energy resources;

- thirdly, global climate changes and the need to reduce greenhouse gas emissions, the growth of which is caused by man-made emissions from energy sector facilities.

Analysis of the dynamics into alternative energy development in Russia shows that our country is currently far behind not only the leading countries but also the Eastern Europe countries. There is a worldwide rapid growth of renewable energy sources (RES). The RES share in energy production for the period of 2003-2018 increased from 2% to 10%. It is expected to 11.2% in 2020. The alternative energy share in the Russian energy sector was approximately 0.3% in the installed capacity of the Russian UES and 0.1% in the structure of electricity generation in 2018.

Today, the main problem in the modern alternative energy development in Russia is the low level of its financing. According to the forecasts of the international energy agency (IEA), Russian energy needs investment in the amount of $2.7 trillion for the period from 2014 to 2035.

Examining the countries' experience that have achieved impressive success in the field of "greening" the economy, we can note that environmental costs were: in Germany – 0.6% of GDP, in the Netherlands-1.4% of GDP, in France-1% of GDP, in Japan-1.2% of GDP. As for Russia, the share of environmental protection costs has not changed much since 2009 (0.7% of GDP). According to some experts, it is necessary to spend at least 1.3% of GDP on forming a "green" finance system every year in Russia to achieve significant success into this field (Panda, 2017).

According to Rosstat data, the results into the field of the "green" economy investment in Russia are significantly demonstrated by the dynamics of the investments' volume in fixed capital. They were aimed at environment protection and rational use of natural resources in 2000-2017. Figure 2 illustrates this process over the past 18 years.

The studied period of 2008-2010 shows a negative trend. It is characterized by a relative increase in "green" investments. At the same time, Russia tried to maintain the priority of investments in fixed capital aimed at the environmental protection and rational use of natural resources even in the crisis years (2008-2009). The dominant volume of investments in fixed capital aimed at environmental protection and rational use of natural resources during the analyzed period was in 2014.
Fig. 2. Investments' dynamics in fixed capital aimed at environmental protection and rational use of natural resources in 2000-2018, million rubles.
Source: compiled by the authors, based on the data of Federal State Statistic Service of Russia

It is important to note that the main amount of funds during the study period was mainly addressed to the water resources' protection. The year 2018 has become more significant due to changes into existing trends in terms of investment directions. The investments in air protection have become the most significant.

The structure of financing sources for "green" investments is specific in Russia. It is significantly that the basic flow of "green" investments in Russia is provided by the own enterprises funds' expenses in contrast to foreign countries. The main investors of "green" investments are the specialized manufacturers and the public sector (see Fig. 3).
Fig. 3. Sources' structure for "green" investments' financing in Russia in 2005-2018, %
Source: compiled by the authors, based on the data of Federal State Statistic Service of Russia

In the study's continuation about the "green" investments in Russia, the attention is drawn to the peculiarities of their distribution by the economic activity type. The priority of the most "green" countries is investment in the production and distribution of electricity, gas, water and manufacturing (100% of total green investment). Unlike of them, the metallurgical production, coke and petroleum
